

CENTRAL STATISTICAL OFFICE

Economic Trends

**No 459
January 1992**

London: HMSO

Introduction

Economic Trends brings together all the main economic indicators. It contains three regular sections of tables and charts illustrating trends in the UK economy.

'Latest developments' presents the most up-to-date statistical information available during the month. It is important to note that data included in this section may not be wholly consistent with other sections which have gone to press earlier. All data in this section are seasonally adjusted unless otherwise stated. In most cases estimates are provisional and subject to revision.

The main section is based on information available to the CSO on the date printed at the foot of this page and shows the movements of the key economic indicators. The indicators appear in tabular form on left hand pages with corresponding charts on facing right hand pages. Colour has been used to aid interpretation in some of the charts, for example by creating a background grid on those charts drawn to a logarithmic scale. Index numbers in some tables and charts are given on a common base year for convenience of comparison.

The section on cyclical indicators shows the movements of four composite indices over 20 years against a reference chronology of business cycles. The indices group together indicators which lead, coincide with and lag behind the business cycle, and a short note describes their most recent movements. The February, May, August and November issues carry further graphs showing separately the movements in all of the 27 indicators which make up the composite indices.

In addition, quarterly articles on the national accounts appear in the January, April, July and October issues, and on the balance of payments in the March, June, September and December issues. Occasional articles comment on and analyse economic statistics and introduce new series, new analyses and new methodology.

Economic Trends is prepared monthly by the Central Statistical Office in collaboration with the statistics divisions of Government Departments and the Bank of England.

Notes on the tables

1. The statistics relate mainly to the United Kingdom; where figures are for Great Britain only, this is shown on the table.
2. Similarly, almost all quarterly data are seasonally adjusted; those not seasonally adjusted are indicated by NSA.
3. Some data, particularly for the latest time period, are provisional and may be subject to revisions in later issues.
4. Rounding may lead to inconsistencies between the sum of constituent parts and the total in some tables.
5. A line drawn across a column between two consecutive figures indicates that the figures above and below the line have been compiled on different bases and are not strictly comparable. In each case a footnote explains the difference.

6. 'Billion' denotes one thousand million.

7. There may sometimes be an inconsistency between a table and the corresponding chart, because the data may be received too late to update the chart. In such cases it should be assumed that the table is correct.

8. There is no single correct definition of *money* and there are many liquid assets which are not included in any of the UK monetary aggregates but which nevertheless need to be taken into account on occasions when interpreting monetary conditions. Consequently, many definitions of money stock are widely used:

M0 the narrowest measure consists of notes and coin in circulation outside the Bank of England and bankers' operational deposits at the Bank.

M2 comprises notes and coin in circulation with the public *plus* sterling retail deposits held by the UK private sector with UK banks, with building societies and in the National Savings Bank ordinary account.

M4 comprises notes and coin in circulation with the public, together with all sterling deposits (including *certificates of deposit*) held with UK banks and building societies by the rest of the private sector.

M5 is equal to **M4** *plus* private sector holdings of certain money-market instruments, CTDs, and some national savings instruments.

9. Symbols used:

.. not available

- nil or less than half the final digit shown

+ alongside a heading indicates a series for which measures of variability are given in the table on page 76

† indicates that the data has been revised since the last edition;

the period marked is the earliest in the table to have been revised

* average (or total) of five weeks.

The Editor would welcome readers' suggestions for improvements to *Economic Trends*.

Central Statistical Office, 4 February 1992

CSO Databank

Virtually all the series in *Economic Trends* and the Quarterly Articles may be obtained as part of the CSO Databank Service on tape or disk. The appropriate four digit identifier is included at the top of the column or start of a row of figures. This enables users to obtain (in computer-readable form) a much more comprehensive and up-to-date set of long run macro-economic time series data than can be included in this publication. The tape format, unlabelled EBCDIC, is the same for all datasets. The disks, either 3½" or 5¼" are written in ASCII text which can be loaded as spreadsheets and viewed using standard spreadsheet packages, such as LOTUS or SMART.

Details of the service offered and the schedule of charges may be obtained from the Databank Manager, CSO Branch 16, Room 52/4, Government Offices, Great George Street, London, SW1P 3AQ (telephone 071-270 6386). CSO does not offer direct on-line access for these data but a list of host bureaux offering such a facility is available on request from CSO.

NEW DIRECTOR FOR CSO

The Prime Minister, with the agreement of the Chancellor of the Exchequer, has approved the appointment of Mr William McLennan as Director of the Central Statistical Office and Head of the Government Statistical Service following an open competition. Mr McLennan will succeed Sir Jack Hibbert when he retires at the end of February 1992. Mr McLennan is 49 years old and was born and educated in Australia. Since 1986 he has been the Deputy Australian Statistician.

The Director is Chief Executive of the Central Statistical Office (CSO) which became a Next Steps Executive Agency on 19 November 1991. It currently employs some 1,100 staff, located in London, Watford and Newport, Gwent. This will increase to some 1,280 during 1992-93, primarily as a result of the further package of measures to improve the quality of economic statistics announced by the Chancellor of the Exchequer on 19 November.

The Head of the Government Statistical Service has responsibilities as the Government's chief adviser on statistics and as the Head of Profession for government statisticians. The chief adviser has the right of access to the Prime Minister, through the head of the Home Civil Service, on matters concerning the validity and integrity of government statistics as a whole.

Mr McLennan obtained an honours degree in

economics, specialising in statistics, from the Australian National University, Canberra, in 1963, while studying under a public service scholarship (a statistics cadetship). He is a career statistician, having worked since graduation in the Australian Bureau of Statistics (ABS), a centralised statistical agency employing 3,300 permanent staff with an annual budget equivalent to £75 million.

As Deputy Australian Statistician since 1986, he has had the role of helping to manage the ABS so as to ensure the regular and timely supply of relevant and accurate statistics. He has been actively involved in corporate planning; in managing the strategic impact of computing upon ABS operations; in marketing statistics; and in international statistical activities.

The Director of the CSO is a Second Permanent Secretary (Grade 1A) post.

UK NATIONAL ACCOUNTS: THE THIRD QUARTER 1991

This article presents quarterly estimates of national income, expenditure and output to the third quarter of 1991. All commentary and charts are in terms of seasonally adjusted data. Estimates of the components of GDP at constant prices are given here in terms of average 1985 prices. Summary estimates of GDP for the third quarter of 1991 were first issued on 20 December 1991.

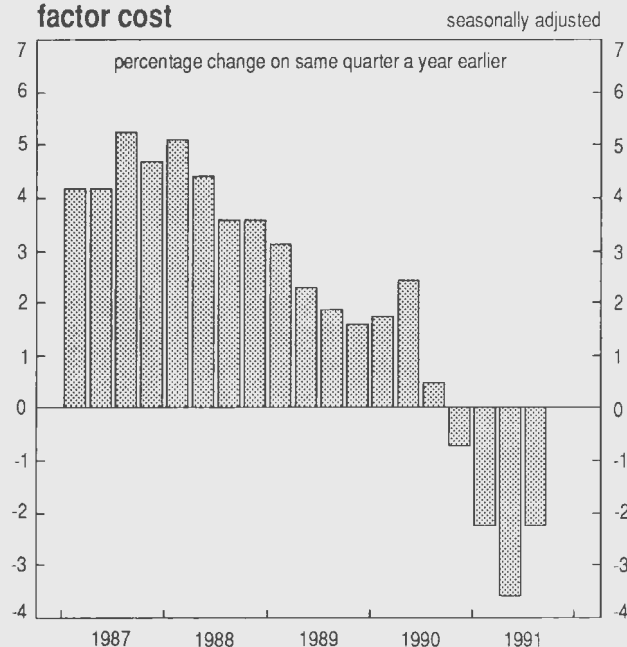

A short description of the United Kingdom national accounts is given as the introduction to the 1991 Edition of *"United Kingdom National Accounts"*, otherwise known as *"the CSO Blue Book"*. More detailed information is available in *"United Kingdom National Accounts: Sources and Methods"* (HMSO 1985) and subsequent changes to sources, methods and definitions are described in the methodological notes to the 1991 CSO Blue Book.

Gross domestic product at current and constant prices

Gross domestic product (GDP) at constant 1985 factor cost increased 0.2 per cent between the second and third quarters of 1991 but was 2.3 per cent lower than in the third quarter of 1990.

Chart 1 shows recent increases in GDP each quarter compared with the same quarter a year earlier. Chart 2 shows increases in GDP, for each quarter on a quarter earlier.

Chart 1
GDP at constant 1985
factor cost

Fluctuations in the output of the oil and gas extraction industries in recent quarters obscure the profile of changes in the level of activity elsewhere in the economy. The analysis of GDP by category of output indicates that, excluding oil and gas production, GDP fell 0.4 per cent between the second and third quarters of 1991 following a similar fall between the previous two quarters.

Chart 2
GDP at constant 1985
factor cost

GDP at current market prices - also known as "money GDP" - was 1.1 per cent higher in the third quarter of 1991 than in the second quarter and 4.5 per cent higher than in the third quarter of last year.

The implied factor cost GDP deflator ("index of total home costs") rose by 5.5 per cent between the third quarters of 1990 and 1991, including an increase of 0.7 per cent between the latest two quarters.

The real income of the United Kingdom, as shown by gross national disposable income at constant market prices, fell 0.4 per cent between the second and third quarters of 1991 and was 2.3 per cent lower than a year earlier.

Estimates of GDP at current and constant prices, of real national disposable income and of the implied GDP deflator are given in index number form in Table A. This is supplemented by information presented in Table 1 of the Appendix.

Revisions to GDP estimates and the main components, since the last set of quarterly estimates appeared in the October 1991 issue of *Economic Trends*, are described later in this article.

Estimates of GDP at constant factor cost are at constant 1985 factor cost, following both UK and recommended international practice of rebasing every five years using the years ending 0 and 5 as the reference year. Since 1985, the relative prices of various goods and services have changed, including a very large reduction in oil prices up to the third quarter of 1990. The implications of this reduction for interpretation of GDP growth assessments are outlined in the Notes at the end of this article.

	Value indices at current prices		Volume indices at 1985 prices			Implied gross domestic product deflator ⁴	
	Gross domestic product at market prices ²	Gross domestic product at factor cost	Gross national disposable income at market prices ³	Gross domestic product at market prices	Gross domestic product at factor cost	At market prices	At factor cost ⁵

Percentage change, latest quarter on corresponding quarter of previous year							
1991 Q3	4.5	3.1	-2.3	-2.2	-2.3	6.9	5.5

1 These estimates are given to one decimal place but this does not imply that they can be regarded as accurate to the last digit shown.

2 "Money GDP".

3 Also known as Real national disposable income (RNDI).

4 Based on sum of expenditure components of GDP at current and constant prices.

5 Also known as the Index of total home costs.

Expenditure at constant 1985 prices (Table A2)

At constant prices, consumers' expenditure remained broadly the same in the third quarter of 1991 as in the previous quarter but was 2½ per cent lower than in the same period of 1990. General government final consumption increased ½ per cent between the second and third quarters of 1991 to a level 1½ per cent higher than a year earlier. Fixed investment was 2½ per cent down in the third quarter of 1991 compared with the previous quarter and 11 per cent lower than a year earlier. The level of stocks was broadly unchanged on the previous quarter.

At constant 1985 prices, total domestic expenditure (which is the sum of consumers' expenditure, general government final consumption, fixed investment and stockbuilding) increased by ½ per cent between the second and third quarters of 1991 but was 3 ½ per cent down on a year earlier. Net imports of goods and services, worth £2.7 billion at constant 1985 prices in the third quarter of 1991, were up from £2.0 billion on the second quarter but down from £4.0 billion in the third quarter of 1990.

Income at current prices (Table A3)

Income from employment in the third quarter of 1991 increased 1 per cent compared with the second quarter of 1991 and was 4 ½ per cent up compared with the third quarter of 1990.

The gross trading profits of the corporate sector were lower than in the previous quarter and around a tenth lower than in the third quarter of last year. Separate comparisons of the gross trading profits of companies and the gross trading surplus of public corporations over these periods are affected by the privatisation of the electricity companies between December 1990 and June 1991.

Output at constant 1985 prices (Table A4)

The output of the production industries increased by 1 per cent between the second and third quarters of 1991. Within production, the output of the energy and water industries up 4 per cent but manufacturing output was broadly unchanged. There was a drop of 2 per cent in the output of the construction industry. Over the same period the total output of the service industries remained broadly the same.

After seasonal adjustment, output of the energy sector, excluding oil and gas extraction, fell 4 per cent between the second and third quarters of 1992. This reflected the unseasonably cold weather in the second quarter and the above average temperatures in the third quarter.

Between the third quarters of 1990 and 1991, the output of the production industries fell 2½ per cent made up of a 7 per cent increase in the output of the energy and water industries and a 5 ½ per cent drop in the output of the manufacturing industries. Over the same period, construction output fell 9½ per cent and the output of service industries was down by 1½ per cent. Within the service industries, the output of the distribution, hotels and catering industries was down 2½ per cent, transport and communications industries was down 3½ per cent and the output of other service industries' down 1 per cent.

Personal income and saving (Table A7)

Real personal disposable income (RPDI) was broadly unchanged between the second and third quarters of 1991 but ½ per cent lower than a year earlier.

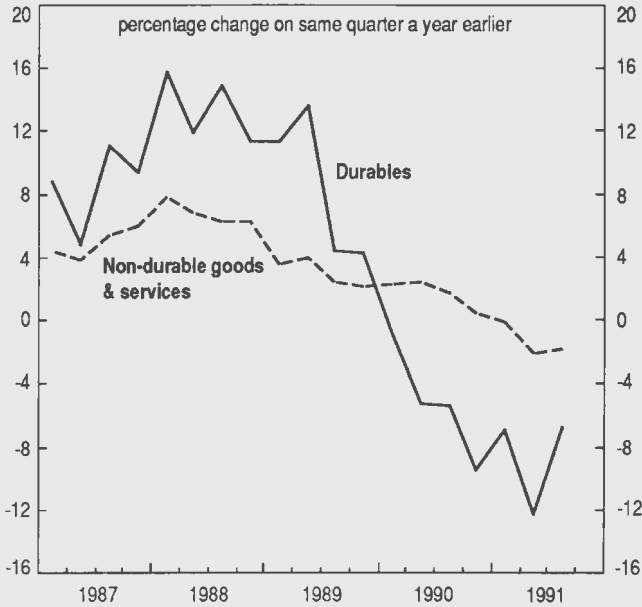

Chart 3
Personal sector saving ratio
percent, seasonally adjusted

Total personal income before deductions, at current prices, grew 5½ per cent between the third quarters of 1990 and 1991. Within this total, wages and salaries rose by 4 per cent, employers' contributions by 6 per cent, current grants from general government increased 16 per cent and other personal income, which includes dividends, increased 3 per cent. Between the second and third quarters of 1991, total personal income grew by 1 per cent.

The saving ratio was 11 per cent in the third quarter of 1991, the same level as in the previous quarter but up from 9½ per cent in the third quarter of 1990. The saving ratio over recent years is shown in Chart 3.

Chart 4
Consumers' expenditure
1985 prices, seasonally adjusted

Consumers' expenditure (Table A8)

At constant prices, consumers' expenditure remained broadly unchanged between the second and third quarters of 1991. In the latest quarter, expenditure on durable goods was up 4 per cent while on services it remained broadly the same and spending on non-durable goods was down by 1 per cent. Spending on energy fell 6½ per cent following the unseasonably cold weather in the second quarter. Chart 4 shows the growth of consumers' expenditure on durable goods and on other goods and services.

Between the third quarters of 1990 and 1991, consumers' expenditure at constant prices fell 2½ per cent. Within this total, expenditure on durable goods showed a 7 per cent fall and expenditure on non-durable goods declined 1 per cent. Amongst durable goods, expenditure on vehicles fell by 15 per cent while expenditure on furniture and floor coverings increased by ½ per cent. Among non-durable items, spending on clothing declined by ½ per cent and on footwear by 4½ per cent but spending on food increased by 2 per cent. Over the same period, spending on energy products fell by 1½ per cent, and expenditure on services dropped by 3 per cent.

Industrial and commercial companies (Table A10)

It is estimated that, after deducting stock appreciation, UK trading profits of industrial and commercial companies changed little between the second and third quarters of 1991. Quarterly estimates of UK trading profits of these companies include quarterly alignment adjustments, which are described in the Notes at the end of this article. In recent years, the sector has been increasing in coverage owing to the privatisation of many public corporations.

Between the latest two quarters, gross trading profits (net of stock appreciation) of North Sea oil companies increased by a quarter to a level 12 per cent higher than a year earlier.

The gross trading profits (net of stock appreciation) of non-North Sea industrial and commercial companies are estimated at £16.4 billion in the third quarter of 1991, little changed from the second quarter or from the third quarter of 1990.

UK industrial and commercial companies' rent and non-trading income from UK sources were up by 1 per cent between the second and third quarters of 1991, and their income from abroad rose by 4 per cent.

Payments of dividends on ordinary shares (excluding payments by UK subsidiaries to their overseas parent companies, and net of payments to other UK industrial and commercial companies) were £5.8 billion. This series is erratic, and quarter to quarter movements should be treated with caution.

Payments of UK taxes on income in the third quarter of 1991 were 14 per cent lower than in the second quarter and a third lower than a year earlier. Profits due abroad in the third quarter of 1991 were 4 per cent higher than in the second quarter but a fifth lower than a year earlier.

These preliminary estimates suggest that the broad measure of UK industrial and commercial companies' undistributed income (that is, before deducting stock appreciation or net unremitted profits) was £9.4 billion in the third quarter of 1991 compared with £10.1 billion in the second quarter and £8.5 billion in the third quarter of the previous year.

Public corporations (Table A12)

Provisional estimates suggest that the gross trading surplus of public corporations (after deducting stock appreciation) are lower in the third quarter of 1991 than in the second quarter. Comparisons over recent quarters are, however, affected by the privatisations of the electricity distribution companies in England and Wales in December 1990, the electricity generation companies in England and Wales in March 1991 and the Scottish electricity companies in June 1991. In addition, National Health Service Trusts are included in this sector from their establishment in April 1991.

Central government (Table A13)

Seasonally adjusted total central government receipts were broadly unchanged between the second and third quarters of 1991. Taxes on income fell by 2 per cent while taxes on expenditure rose by 2 per cent. Net receipts of national insurance contributions declined by 3 per cent.

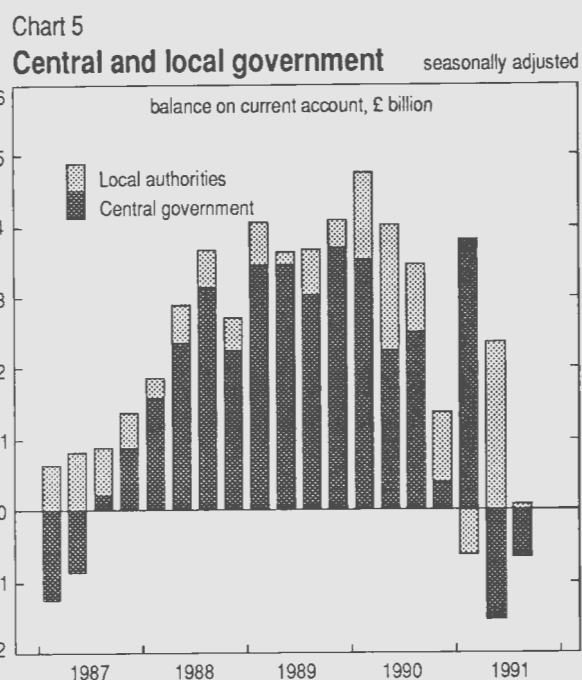

Total current expenditure of central government fell by 1 per cent between the second and third quarters of 1991. Within this total, expenditure on final consumption (military defence, health services, etc) rose by 1 per cent but expenditure on subsidies, grants and debt interest combined fell by 2 per cent.

Local authorities (Table A14)

Total current receipts of local authorities were 11 per cent lower in the third quarter of 1991 than in the second quarter but 5 per cent higher than in the third quarter of 1990.

Total current expenditure rose 12 per cent between the third quarters of 1990 and 1991 with expenditure on final consumption up 9 per cent over this period and expenditure on subsidies, grants and debt interest combined up 21 per cent. The surplus on the current account was £75 million in the third quarter of 1991 compared with £950 million a year earlier.

The quarterly balances on the current accounts of central government and local authorities over recent years are shown in Chart 5.

International transactions (Tables A15 and A16)

At current prices, exports of goods were 4 per cent higher in the third quarter of 1991 compared with the third quarter of 1990 and exports of services were 6 per cent higher. Property income from abroad fell by 4 per cent over the same period and total UK current account credits, including transfers, increased by 2 per cent.

At current prices, imports of goods fell by 2 per cent between the third quarters of 1990 and 1991 but imports of services increased by 2 per cent. Over the same period property income paid abroad increased 1 per cent but overall UK current account debits, including transfers, were broadly unchanged.

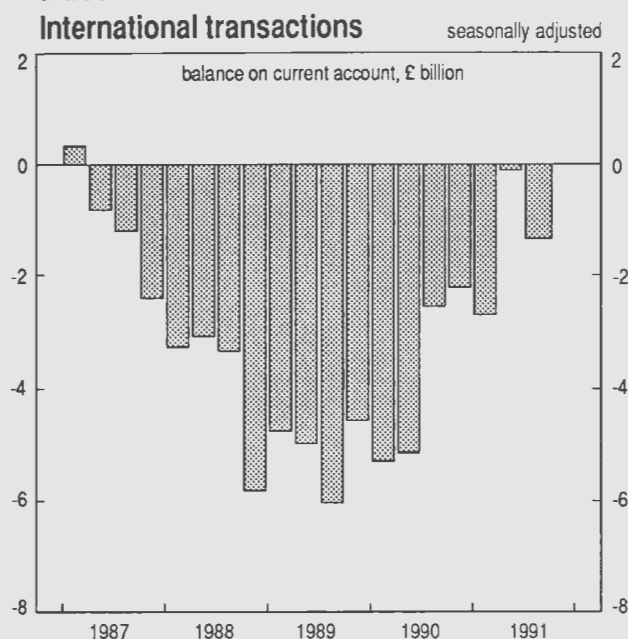

Trends in the quarterly current account balance over recent years are shown in Chart 6.

At constant 1985 prices, exports of goods rose 5 per cent in the third quarter of 1991 compared with a year earlier, but exports of services were 2 per cent lower. Over the same period imports of goods were 1 per cent lower and imports of services declined by 3 per cent.

Gross domestic fixed capital formation at 1985 prices (Tables A17 and A18)

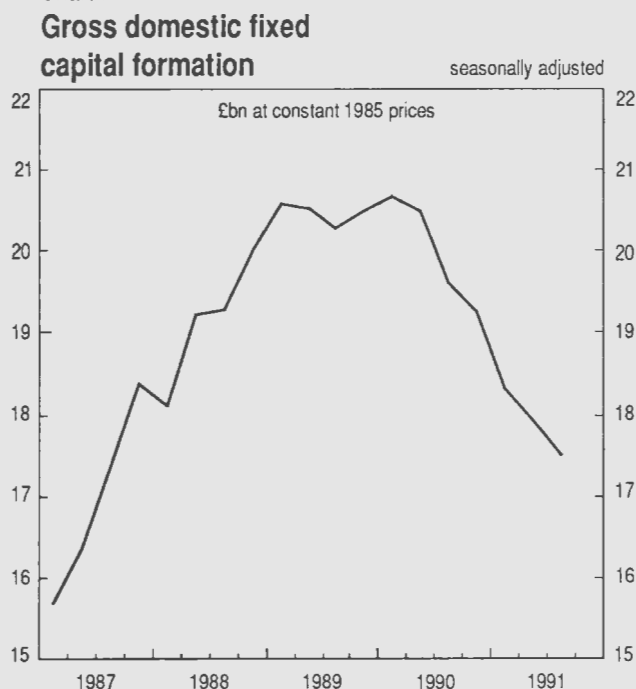

Total fixed investment is estimated to have been 11 per cent lower in the third quarter of 1991 than a year earlier. Fixed investment by

Chart 6

the private sector fell by 11 per cent, whilst that by general government rose by 1 per cent. Over the same period, fixed investment by public corporations declined by around half (though this comparison is somewhat distorted by privatisations). The quarterly profile of fixed investment over recent years is shown in Chart 7.

Chart 7

Analysed by asset, fixed investment fell between the third quarters of 1990 and 1991 for each type of asset.

Value of physical increase in stocks and work in progress at 1985 prices (Table A19)

The destocking of the previous three quarters has ceased. This reflects, in particular, reduced destocking in manufacturing and some stockbuilding in retailing.

Revisions (Table A20)

Estimates of GDP are subject to revision as more information becomes available. Table A20 compares latest estimates with those in the quarterly article on UK national accounts in the October 1991 edition of *Economic Trends*.

GDP at constant 1985 factor cost has been revised upwards by £500 million in 1990. Amongst the income components there has been a downwards revision to income from employment which has been partly offset by an upwards revision to gross trading profits of companies.

NOTES

CSO has indicated for several years that the average of estimates compiled on the expenditure, income and output approaches to the measurement of GDP should be regarded as the definitive estimate. From now on, the CSO will be phasing out references to different measures of GDP. All reference to GDP in this and subsequent CSO publications, relate to the average measure which will be called simply GDP. The CSO will of course continue to publish GDP analysed by its income, expenditure and output components. Table A21 shows value and volume indices and levels for the former individual measures.

Interpretation of estimates at market prices

GDP estimates, and those for consumers' expenditure, have been affected since the second quarter of 1989 by the abolition of domestic rates in Great Britain and the introduction of the community charge. In national accounts, domestic rates are classified as a tax on expenditure whereas the community charge is treated as a deduction from income.

Estimates of consumers' expenditure, GDP and GNP aggregates at current market prices for the second quarter of 1989 onwards are therefore lower than they would have been if the community charge had not replaced domestic rates. A fuller description of the change in the series appeared in the August 1989 issue of *Economic Trends* (No 430).

Interpretation of estimates at constant prices

In the interpretation of quarterly and annual national accounts estimates, special attention needs to be paid to the higher margins of error attaching to series estimated at constant prices when the rate of inflation is changing significantly. Movements in exchange rates may also affect the valuation of international transactions.

National accounts estimates at constant prices are made at average 1985 prices and indices calculated in terms of 1985=100. Interpretation of estimates at constant prices should bear in mind that the choice of base year can affect significantly assessment of GDP growth rates where sharp changes in relative prices occur. In this connection it may be noted that the relative price of oil products was much higher in 1985 than today, with the result that GDP estimates at constant 1985 prices give a much larger weight to the recent variations in the UK oil production than would be the case if estimates of GDP at constant prices were made in terms of a more up to date price structure.

In order to achieve coherence between the output, expenditure and income approaches to measurement of gross domestic product, some modifications have been made to the initial estimates of various components within the likely error range of the data. In particular, the annual estimates of income from employment, have been reduced by £1000 million in 1988 and £1500 million in 1989; estimates for self-employment income (included within Other personal income) have been reduced by £300 million in 1989 and increased by £700 million in 1990; estimates of the gross trading profits of non-North Sea industrial and commercial companies have been reduced by £800 million in 1986, £1,200 million in 1987, £1,600 million in 1988 and £200 million in 1989; they have been increased by £900 million in 1990, and this has been projected forward into 1991. Upward modifications have also been made to the annual estimates of stockbuilding from 1988 onwards.

Quarterly alignment adjustments

To improve the coherence of the quarterly accounts, some adjustments are made to quarterly estimates of both the expenditure and income analyses of GDP for 1983 onwards. These adjustments, which sum to zero across each of the years 1983 to 1990, are attributed to the stockbuilding component of GDP analysed by expenditure and to gross trading profits of companies in the income analysis, where accurate measurements are most difficult.

These quarterly adjustments modify the aggregates derived from expenditure or income components so that they better reflect the quarter to quarter paths suggested by output. (CSO has always indicated output estimates yield the best short term indicator of growth). For profits the alignment adjustments are constrained within the likely error range attaching to the estimated quarterly path of profits. The impact of this constraint on the quarterly path of GDP, which is calculated as the average of expenditure, income and output analyses, is small.

The alignment adjustments included in estimates in this article are shown in Table B.

Appendix Tables

The tables in the Appendix give series of quarterly figures back to 1988. Where an obelus appears this indicates that the data are new or have been revised, with the period so marked the earliest to have been revised. If the obelus appears against the first figure in a column, this implies that earlier data may also have been revised. Such earlier data can be obtained from the CSO Databank, which contains all of the series given in the Appendix tables.

Table B
Quarterly alignment adjustments

The CSO Databank

The data in these tables can be obtained in computer readable form via the CSO Databank service which provides macro-economic time series data on magnetic tape and floppy disk. Each series on the Databank is allocated a four letter identifier which appears in the Appendix tables at the head of each column of data. The Databank enables users, host bureaux and end users to have a longer run of the data than can be included in the tables.

Details of the service offered and the Schedule of charges may be obtained from the Databank Manager, CSO Branch 16E, Room 52A/4, Government Offices, Great George Street, London SW1P 3AQ (Telephone: 071-270 6386 or 6387). CSO does not offer direct on-line access for these data, but a list of host bureaux offering such a facility is available on request from CSO.

1 Estimates are given to the nearest £ million and in case of indices to one decimal place but cannot be regarded as accurate to this degree. Estimates at current market prices are affected by the abolition of domestic rates and the introduction of the community charge.

2 Equals taxes on expenditure less subsidies.

3 The factor cost estimate of GDP is obtained from the market price estimate by subtracting the factor cost adjustment.

4 Gross national product equals Gross domestic product plus Net property income from abroad.

5 Represents Taxes on expenditure less Subsidies both valued at 1985 prices.

1 Estimates cannot be regarded as accurate to the last digit shown.

2 Any differences between this column and the data on page 28 arise because the latter may be based on later information.

3 Embraces an implicit statistical discrepancy compared with the sum of the previous columns, because GDP takes account of other information based on incomes and expenditures.

1 These estimates are given to one decimal place but this does not imply that they can be regarded as accurate to the last digit shown.

2 "Money GDP".

3 Also known as Real national disposable income (RNDI).

4 Based on sum of expenditure components of GDP at current and constant prices.

5 Also known as the Index of total home costs.

1 The residual error is, by convention, the amount by which the expenditure-based approach to measuring GDP exceeds the income-based estimate. It is also the sum of two components: the Statistical discrepancy (expenditure) with sign reversed, and the Statistical discrepancy (income) with natural sign.

2 Equals the Statistical discrepancy (expenditure) with sign reversed.

3 Equals the Statistical discrepancy (income) with the same sign.

1 Before providing for depreciation and stock appreciation.

2 Equals total personal income before tax less payments of taxes on income, social security contributions and other current transfers.

3 Before providing for depreciation, stock appreciation and additions to tax reserves.

4 This series is affected by the abolition of domestic rates and the introduction of the community charge (see notes at the end of the article).

5 Personal saving as a percentage of total personal disposable income.

6 Personal disposable income revalued by the implied consumers' expenditure deflator (1985 = 100).

1 Figures reflect privatisation of British Telecom with effect from 28 November 1984, British Gas from 3 December 1986, British Airways from 6 February 1987, Royal Ordnance from 22 April 1987, BAA from 16 July 1987, British Steel from 2 December 1988, water companies from 12 December 1989, electricity distribution companies from 11 December 1990, electricity generating companies from 12 March 1991 and Scottish electricity generating companies from 18 June 1991.
2 Quarterly alignment adjustment included in this series. For description of this adjustment, see Notes.
3 Before providing for depreciation.

4 Dividend payments on ordinary and preference shares are net of tax; the advance corporation tax in respect of such payments is included in 'UK taxes on income'. Excludes dividends and debenture interest paid by UK subsidiaries to their overseas parents.

5 Including royalties and licence fees on oil and gas production.

6 Mainly payments of corporation tax (including advance corporation tax), petroleum revenue tax and supplementary petroleum tax.

7 Before providing for depreciation, stock appreciation and additions to reserves.

1 Before providing for depreciation and stock appreciation.

2 This represents the contribution of financial companies and institutions to the gross domestic product. It is the difference between bank charges, commissions, etc., on the one hand and management expenses (wages and salaries and payments for current expenses) on the other.

3 Dividend payments on ordinary and preference shares are net of tax; the advance corporation tax in respect of such payments is included in 'UK taxes on income'. Excludes dividends and debenture interest paid by UK subsidiaries to their overseas parents.

4 Before providing for depreciation, stock appreciation and additions to reserves.

1991 Q3	-5.3	13.0	5.6	6.1		-41.7	-14.0	2.1	-48.7	9.8	4.0

1 Tax receipts less tax credits.

2 Includes, from second quarter 1990 accruals of National Non-domestic Rates which are treated as a central government tax.

3 This series is affected from second quarter 1990 by change in the non-domestic rating system (see notes).

4 These include contributions to the Maternity Pay Fund and contributions from employees.

5 Before providing for depreciation and stock appreciation.

6 Including royalties and licence fees on oil and gas production.

1 This balance is equal to savings plus capital transfers less gross domestic formation.

2 Before providing for depreciation, stock appreciation and additions to reserves.

3 Equal to stock appreciation plus value of physical increase in stocks and work in progress.

4 Equals, apart from the change in sign, the financial surplus or deficit of the overseas sector.

5 Excluding financial transactions on the writing-off of debt.

6 Gross and net fixed capital formation by the personal sector excludes that by Life assurance and pension funds: this is included with that of Financial companies and institutions.

7 Figures for companies and public corporations are affected by privatisation.

1 Estimates are given to the nearest £ million but cannot be regarded as accurate to this degree.

2 The industry analysis of Gross domestic fixed capital formation includes vehicles, ships and aircraft, plant and machinery as well as new buildings and works other than dwellings. It excludes fixed investment in dwellings and the transfer costs of land and existing buildings.

3 The numbered Divisions referred to are those of the Standard Industrial Classification, Revised 1980.

4 Including transfer costs of land and existing buildings.

1 For years up to and including 1982, the totals differ from the sum of the components because of the method used to rebase on 1985 prices.

2 Further details are given in the *Monthly Digest of Statistics*.

3 Excluding wholesale distribution of motor vehicles, parts and accessories.

4 Excluding retail distribution of motor vehicles and parts, and filling stations.

5 Quarterly alignment adjustment is included in this series. For description of this adjustment, see notes.

6 Differences between totals and the sum of constituent parts of manufacturing are due to rounding.

7 Book values of stocks on left hand side, constant 1985 prices on right.

8 First and second quarter 1989 estimates include adjustments (+£300m and -£300m respectively) to offset distortion to total stocks estimates otherwise caused by Easter falling in March 1989.

1 The Residual error is, by convention, the amount by which the expenditure-based approach to measuring GDP exceeds the income-based estimate. It is also the sum of two components: Statistical discrepancy (expenditure) with sign reversed, and the Statistical discrepancy (income) with natural sign.

2 Income data deflated by the implied GDP deflator at factor cost, based on expenditure data.

INTERNATIONAL COMPARISONS OF TAXES AND SOCIAL SECURITY CONTRIBUTIONS IN 20 OECD COUNTRIES 1979 - 1989 ^{1, 2}

Central Statistical Office

This article compares twenty OECD countries on three criteria: **first**, the overall percentage of gross national product, GNP, at factor cost taken by taxes and social security contributions during 1979-1989 (together with preliminary estimates for 1990 of taxes and social security contributions as a percentage of gross domestic product, GDP, at market prices); **second**, the distribution of total taxation among various categories of tax; and **third**, the percentage of household income taken by direct taxes and social security contributions.

All calculations are based on returns made to the OECD (Organisation for Economic Co-operation and Development).

Articles making comparisons of this nature have appeared regularly in *Economic Trends* since 1969, but the earlier articles contained less country detail. The latest article preceding this one was in the November 1990 issue. Detailed figures for each country from 1979 are given in the Appendix, but summary tables are confined to those countries for which the necessary data are available for the three periods shown. Except in Table H, the percentages are derived from data compiled according to standardised international definitions: further information on sources and methods is given in the "Technical notes".

The comparisons are supplemented by "Technical notes" which discuss the limitations of such comparisons, the sources of data, as well as differences between the United Kingdom system of national accounts and international definitions.

It should be noted that all mention of Germany in the text, tables and appendix tables refer to *western* Germany (Federal Republic of Germany before the unification of Germany).

Overall comparisons

1979 to 1989: Taxes and social security contributions as a proportion of total economic activity

Countries vary greatly in the percentage of GNP taken by taxes and social security contributions (see table A). In descending order, Sweden, Denmark and Norway have occupied the first three places, in differing order, in most years since 1979 when looking at the percentage of GNP taken by taxes and social security contributions, and 1989 saw Sweden at the head of the table with taxes and social security contributions equal to 66 per cent of the GNP. The United Kingdom lies tenth with 43 per cent, and the United States and Switzerland both have the lowest figure, 32 per cent. Eleven of the sixteen countries in appendix Table 1 show a fall in the amount of taxes and social security contributions as a percentage of GNP in 1989, compared with the previous year. Comparing 1984 and 1989 there is an equal split between countries reporting increases and decreases in the percentage figures. The most notable increases were reported by Sweden and Italy while the largest decrease was reported by Belgium.

¹ Includes the community charge introduced in Scotland from April 1989

² Former SNA - for details see Technical note

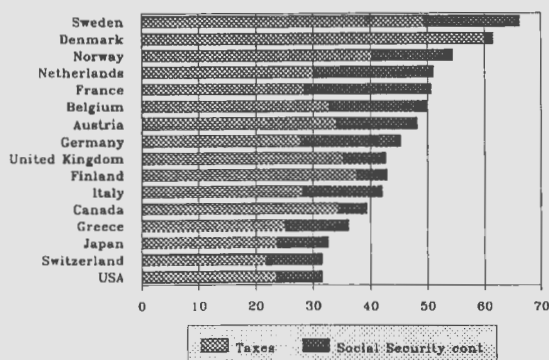

³ Excludes the community charge

An assessment on taxes alone, that is excluding social security contributions, can yield marked differences in the rankings for some countries. This reflects the degree to which taxes are raised by such contributions. Australia has, in the past, had the most marked difference because no separate social security contributions are collected there, but no 1989 data is available for this comparison. The most marked difference in 1989, therefore, is for Canada, which was ranked twelfth when including social security contributions and sixth when excluding them. Similarly, the United Kingdom ranked tenth including and fifth excluding social security contributions. Conversely, those countries

where social security contributions are a substantial part of total tax revenues ranked lower; France, for example, moves from fifth to tenth and the Netherlands from fourth to ninth.

Appendix Table 2 shows the proportion of taxes alone as a percentage of GNP at factor cost, and figure 1, below, shows the relative positions of the sixteen available countries comparing both taxes and social security contributions together, in 1989.

Figure 1: Taxes and social security contributions as a percentage of GNP at factor cost in 1989

In making percentage of GNP at factor cost the main basis of comparison, this article follows the convention adopted for international comparisons in previous articles in this series. For studies of the United Kingdom alone, GDP at market prices is often used as a denominator. On this basis, using published OECD figures for GDP at market prices as in Table B below, the United Kingdom still ranked tenth in 1989 out of the same list of countries; 37 per cent of its market price GDP was taken in taxes and social security contributions.

Table B : Taxes and social security contributions as a percentage of GDP at market prices by rank

Distribution over categories of tax

Direct taxes on households as a share of total taxes and social security contributions

Over the ten year span, as shown in Table C, the Netherlands recorded the largest reduction (5 percentage points) in direct taxes on households as a proportion of total taxes and social security contributions: the United Kingdom shows a fall of 4 percentage points since 1979 to a 1989 level of 27 per cent. Reductions also occurred in Austria, USA, Switzerland and Sweden. In contrast, Denmark recorded the largest increase (6 percentage points). In the United Kingdom, the pattern since 1979 has been downwards in the main although the level has now been around 28 percent for the last six years.

Table C : Percentage of total taxes and social security contributions derived from direct taxes on households¹

	Percentages		
	1979	1984	1989
Denmark	55	58	61
Finland	39	41	42

France	14	15	14

¹ Includes payments made by unincorporated businesses (except for Germany and the Netherlands, but these exceptions do not materially affect the comparisons) and, for those countries which have adopted the SNA, motor vehicle license duties paid by households.

² Former SNA - for details see Technical note

Direct taxes on corporate income as a share of total taxes and social security contributions

Direct taxes on corporate income remained fairly stable over the ten year period as a proportion of total taxation for most of the countries shown, Table D and appendix Table 4 summarise this. Norway provides the main point of interest in Table 4, showing a steep rise to 19 per cent in 1985, followed by a sharp fall to 6 per cent in 1988, then a rise to nearly 8 per cent in 1989: the overall effect from 1979 to 1989 was a fall of around 2 percentage points.

The United Kingdom shows a similar but less dramatic pattern to Norway's: a fairly steady increase in the share from the mid-1970's until 1985 (due mainly to the increasing importance of taxes on North Sea oil profits) followed by a drop of 2 percentage points in 1986 (reflecting a sharp fall in receipts from petroleum revenue tax) to a level of 11 per cent where it has remained until 1989 when it increased to over 12 per cent. In most of the fifteen countries for which the comparison is possible, a slight rise is discernible over the most recent years in the share derived from taxes on corporate income. The most notable exception is Canada, which fell from 11 per cent in 1984 to 8 per cent in 1989.

Indirect taxes as a share of total taxes and social security contributions

The share of total revenue obtained from indirect taxation fell in the majority of the countries listed in Table E. The exceptions to this were Finland, Sweden, Norway, and the Netherlands. Of the countries which have experienced a fall, the largest was in Denmark where indirect taxes as a percentage of total taxes and social security contributions has fallen by 7 percentage points since 1979, to a 1989 level of 36 per cent.

In the United Kingdom, a rise from 43 per cent in 1979 to 44 per cent in 1981 was followed by a slight but steady fall to 41 per cent in 1985. The level then remained around 43 per cent until 1988 before falling to 42 per cent in 1989.

Social security contributions as a share of total revenue

Social security contributions increased as a percentage of total revenue in some two-thirds of the countries for which

estimates are available. This is shown by Table F. Belgium showed the largest rise since 1979 (up 5 percentage points), followed by The United States (up 4 percentage points). Decreases were recorded in Italy, Finland, Japan, and Sweden, with Italy showing the largest fall (7 percentage points), followed by Finland (3 percentage points).

In the United Kingdom, the share has remained steady around 18 per cent since 1983.

Value added tax

Value added tax varies widely in those countries which apply it. The highest level of contributions to total tax and social security contributions can be found in Austria with a figure of 21 per cent for 1989 and the lowest in Sweden with value added tax amounting to 14 per cent. The United Kingdom shows a figure of 17 per cent in 1989.

Taxes on capital

Receipts from taxes on capital have remained virtually static in the majority of the countries shown throughout the last ten years, as demonstrated in the country by country comparison available in appendix Table 4. Most countries show that less than 1 per cent of total taxes and social security contributions is taken by taxes on capital. The exceptions are Greece, Japan and Switzerland which show respective levels of 1, 2 and 3 per cent in the latest year.

The United Kingdom has consistently shown a level of around half a per cent for the last ten years.

Direct taxes on households and social security contributions as a percentage of total personal income

The proportion of household income taken by direct taxes and social security contributions ranges from 14 per cent in Greece up to 37 per cent in Sweden, as shown in Table G. These percentages are influenced by the numerous factors noted in the technical notes on the "limitations of the comparisons".

The treatment of employers' social security contributions also affects these comparisons. In the national accounts, both employers' and employees' social security contributions are considered to form part of personal income. The impact of taxes and contributions, as perceived by the taxpayer, may be better reflected by an alternative approach: that is, to include only employees' contributions to social security schemes in the calculations (excluding employers' contributions from both numerator and denominator). Table G summarises figures on both bases.

¹ Former SNA - for details see Technical note

² Includes the community charge introduced in Scotland from April 1989

The proportion of personal income taken by direct taxes along with total employers' and employees' social security contributions, was higher in 1989 than in 1979 for two-thirds of the countries for which the data are available. The largest increases were in Canada and Japan, up by 4 and 3 percentage points respectively. For the United Kingdom, the share in 1989 was 1 percentage point lower than in 1979. Three other countries saw slight falls in their share of total personal income taken by direct taxes on households and social security contributions.

Excluding employers' social security contributions, tends to reduce the size of the percentage take. These reductions are especially large for Sweden and for France, both showing reductions of 10 percentage points when comparing the figures including and excluding employers' contributions.

Preliminary estimates for 1990

For some member countries of OECD, provisional data for 1990 are available in the latest edition of *OECD Revenue Statistics*. Table H gives a comparison between 1989 and 1990 derived from this source. These figures are not on the same basis as those in the rest of this article.

Table H : Total receipts from taxes and social security contributions as a percentage of GDP at market prices: preliminary estimates for 1990

	Percentages		Difference between 1989 and 1990
	1989	1990	
Sweden	56.1	57.7	1.6
Denmark	49.9	48.1	-1.8
Norway	45.5	46.2	0.7
Netherlands	46.0	45.4	-0.6
France	43.8	43.8	-
Austria	41.0	41.1	0.1
Italy	37.8	39.5	1.7

United Kingdom ¹	36.5	36.8	0.3
Switzerland ²	31.8	31.2	-0.6

¹ Includes community charge introduced in Scotland in April 1989 and in England and Wales from April 1990

² Former SNA - for details see Technical note

Countries contrast widely in the changes shown between 1989 and 1990 in the proportion of GDP taken by taxes and social security contributions. For the United Kingdom there was a increase of 0.3 percentage points compared with an increase of 2.1 percentage points for Canada and a decrease of 1.8 percentage points for Denmark.

These changes do not greatly alter the ranking of the countries other than Italy. Although the corresponding set of estimates on a national accounts basis is not yet available, this is likely to give a similar picture.

Technical notes

1. Limitations of the comparisons

The comparisons made in this article indicate only broadly the relative importance of taxation in different countries. There are various factors which should be kept in mind :

- Total taxation, the form of taxation, and the composition of taxes reflect differences between countries in their economic and financial structures and in the degree of government involvement in providing services and financial support (for example, medical care and retirement pensions).
- Comparisons are also affected by the methods governments choose to achieve their aims, for example: government tax receipts may be reduced through a system of tax reliefs, or a gross system may be adopted under which money is collected in taxes and then handed back as cash grants.
- The extent to which governments finance their expenditure by borrowing or from taxation varies between countries, and over time, and has an effect on the ratios of taxes to the gross national product.
- Including or excluding social security contributions can have a marked effect on comparisons between countries.

The figures shown here relate to total tax yields in each country: they reveal nothing about the incidence of tax on different groups.

2. Sources

The figures in the tables for direct taxes, indirect taxes and social security contributions are based on returns supplied to the OECD by national statistical offices and summarised in *OECD National Accounts 1977 - 1989, Volume Two, Detailed Tables*. These returns are made on the accounting conventions of the international organisations, which differ from those established in the United Kingdom; consequently the estimates made are not in all cases identical to those given in the CSO's own publications. Taxes on capital - which in the OECD national accounts presentation are included indistinguishably in capital transfers - have been derived from *Revenue Statistics of OECD Member Countries 1965 - 1990*. Figures for value added tax have also been obtained from this publication.

In this article, national accounts data have been used as the prime source, because the figures will be the more consistent with other statistics which are frequently derived from the national accounts publication.

3. Differences between OECD national accounts statistics and OECD Revenue Statistics

There are a few minor differences between the definitions of taxes and social security contributions used in Revenue Statistics and those used in the national accounts returns.

The main differences are in the time of recording the transactions. In Revenue Statistics these are recorded at the time the public authority receives the money, but in the national accounts they are entered when due to be paid. The relative positions of the countries are little affected.

Table J shows, in alphabetical order of country, the percentages scored both on an OECD National Accounts basis and on a Revenue Statistics basis. There are small consistent ranking discrepancies in a number of the countries shown. Discrepancies in the higher orders for 1989 reflect the absence of National Accounts data for Australia and Spain for that year.

4. Differences between the United Kingdom system of national accounts, the Former SNA and the Present SNA

The national accounts returns to OECD are based as far as possible on the System of National Accounts introduced by the United Nations in 1968 (the "Present SNA"). However, two countries - Greece and Switzerland - still provide figures on the basis of the previous system (the "Former SNA"). The figures on one basis are not strictly comparable with those on the other but the difference in definitions has little effect on the comparisons made in this article. Belgium has now adopted the "Present SNA" and earlier data for that country has been revised onto the new basis.

The main differences between the United Kingdom system and the international systems are summarised in Table K. United Kingdom figures in this article on a "national accounts" basis have been converted to the Present SNA.

5. The Community charge

The community charge has been included as a separate category of non-discretionary transfer to general government.

THE EFFECTS OF TAXES AND BENEFITS ON HOUSEHOLD INCOME, 1989

The main points are:

- (1) The effect of government expenditure and taxation is to reduce the differences in income amongst households. In 1989 taxes and benefits (including NI pensions) increased the share of total income of the bottom fifth of households from 2.0 per cent of original income to 6.9 per cent of post-tax income (Table C). Cash benefits play the largest part in reducing income differences.
- (2) The joint impact of taxes and benefits is greatest for retired households and for those non-retired households containing no economically active people.

Introduction

The aim of this analysis is to examine how the distribution of income amongst households in the UK is modified as a result of Government expenditure and taxation. During 1989 the Government raised and spent £196 billion; most of this revenue was raised, directly or indirectly, from UK households who also benefited, directly or indirectly, from the associated Government expenditure. In this article over half of this expenditure is allocated to households (see Table 1 in Appendix 1). Although greater equality of incomes is not necessarily a primary aim of this process, it is nevertheless one of its consequences. This article is the latest in an annual series published in *Economic Trends* since the early 1960s. Each year the article covers the same main ground but also usually has a special topic. This year, however, the special topic has been omitted, in order to speed up production of the 1990 article.

Last year (ie 1988 results) we reworked the data for previous years using the new methodology introduced with the 1987 results. The most important change was to introduce equivalisation (ie adjusting income to allow for household size and composition) into the ranking process. The trends in the income distribution over the period 1977-1988, reworked on the new basis, formed last year's special topic.

Equivalisation

Equivalisation means adjusting household income to allow for household size and composition.

For example: consider two married couples, both earning £15,000 a year, the Jones with no children and the Smiths with two children (aged 3 and 5). The Jones have an equivalence factor of 1.00 whereas the Smiths have a factor of 1.39 (where the 0.39 accounts for the children). The Smiths have a lower equivalised income at £10,791 (=£15,000/1.39) than the Jones at £15,000 (=£15,000/1.00).

The contents are as follows:

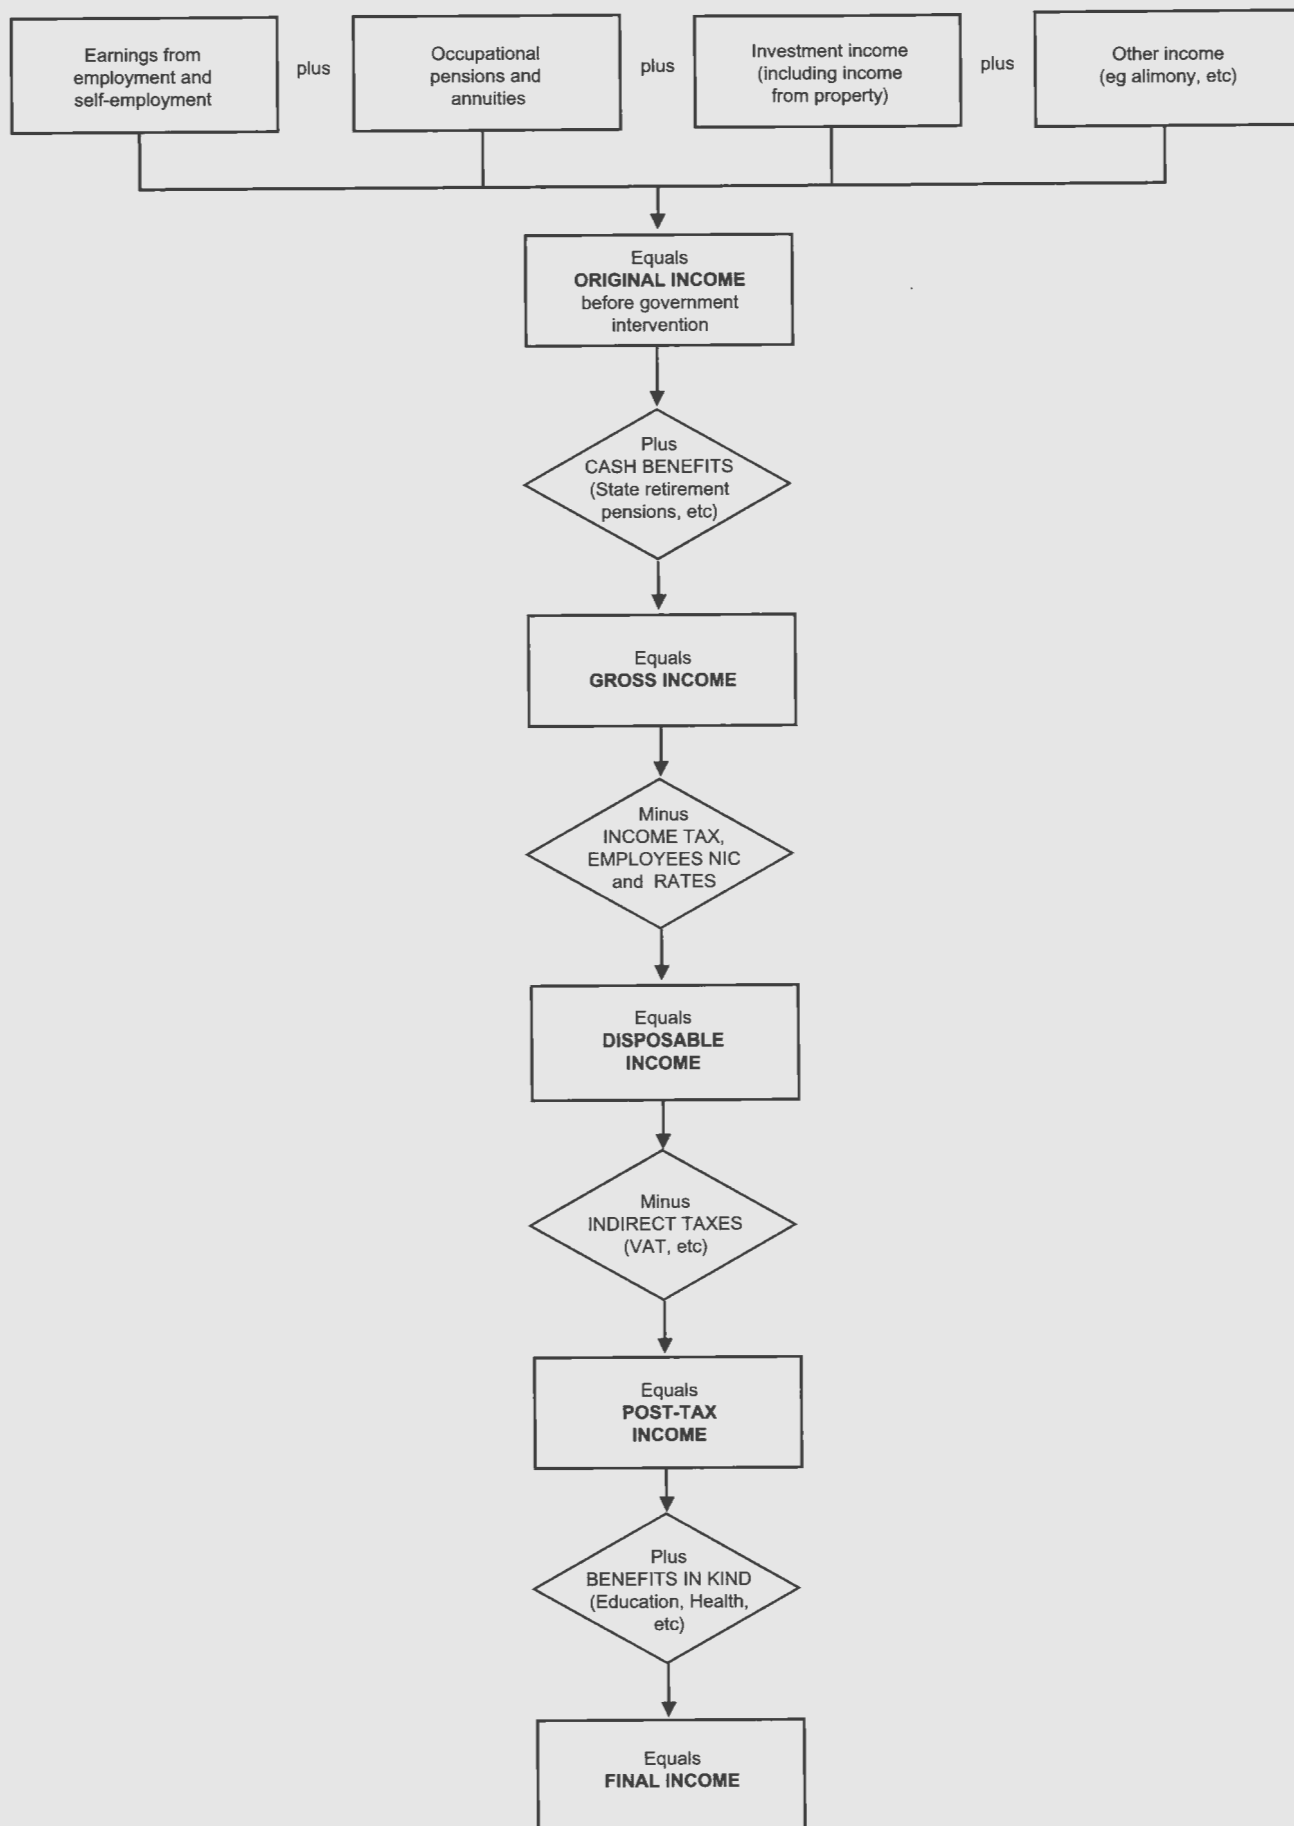

- Main article Results for 1989 for all households, and for retired and non-retired households separately.
- Appendix 1 Detailed tables for 1989, with fine breakdown of income components for quintile and decile groups, and results for different types of household.
- Appendix 2 Methodology and definitions.
- Appendix 3 Three tables for 1989, ranked using *unadjusted* disposable income.
- Appendix 4 Trends in income distribution, 1977-1989.

Background

The main data source is the annual Family Expenditure Survey (FES). Since this article is based on a sample survey, its results are subject to sampling errors. These are generally larger for the smaller household groups (further details on sampling errors and reliability are given in Appendix 2). The unit of analysis is the household, rather than the person or benefit unit. This analysis gives a snapshot of different households at various stages in their lifecycles; it reflects the fact that most people have less income when elderly than at their peak earning age. The monetary values in the tables in the main body of the article are rounded to the nearest £10. The tables generally show actual annual incomes and taxes (ie unadjusted or unequivalised), but some of the appendix tables also give equivalised disposable income values (shown in *italics*) as well. Because not everybody wants to use a distribution ranked by equivalised income, we have also shown three tables ranked by unadjusted disposable income in Appendix 3.

The figures in each year's article are free standing and are not intended to be used as part of a time series with figures from earlier articles. However, Gini coefficients and shares of income are relatively robust and can be used to gauge the trend of income distribution. The philosophy underlying these articles is to use a given year's FES to produce the most meaningful figures for that year (on the basis of the definitions current for the FES at the time), rather than aim to produce figures on exactly the same basis from one year to the next. The FES changes slightly each year, and no special effort has been made in the past to ensure a fully-consistent time series. The major changes to the methodology in the 1987 article mean that the 1987 (and later) figures are completely incompatible with those already published for earlier years.

Studies have indicated that the FES suffers from some non-response bias, for example through under-representation at the very top of the income distribution, the elderly and the self-employed. However, the data presented in this article have not been reweighted to take account of non-response bias, with the exception of some indirect taxes (see below).

Stages of redistribution

Summary of the effects of taxes and benefits, 1989

Economically active people	0.3	0.7	1.4	1.7	1.7	1.2
Retired people	0.7	0.7	0.4	0.2	0.1	0.4

1 All the tables in Part 1 of this article show unequivalised income:equivalised income has only been used in the ranking process to produce the quintile groups (and to produce the percentage shares and Gini coefficients).
2 These are income tax (which is after tax relief at source on mortgage interest and life assurance premiums) and gross domestic rates/Community charge.
3 Children are defined as persons aged under 16 or aged between 16 and 18, unmarried and receiving non-advanced further education.

The data on household income, cash benefits, income tax, National Insurance contributions and domestic rates are used directly from the FES. In contrast, the figures for indirect taxes (eg VAT, duty on beer) and benefits in kind (eg from state education) are calculated using an imputation process - which uses FES data, for example on households' expenditure and characteristics. This imputation process is carried out within the framework of the National Accounts aggregates, and involves many assumptions (for example on incidence and grossing up for non-response on alcohol expenditure). Some of these assumptions are doubtful, and hence the results of this part of the analysis are subject to a wide margin of error. Tables 1 and 2 in Appendix 1 give government expenditure and its financing for 1989, derived from the National Accounts. Appendix 2 gives more detail on the methodology.

MAIN ARTICLE

Chart 1 illustrates the stages of redistribution which form the structure of this analysis. Initially, household members receive income from their employment (wages and salaries, self-employment income); from occupational pensions; from their investments and from other households (eg alimony payments). Total income from these sources constitutes original income. The flow chart shows the various ways in which Government then raises revenue from households and distributes benefits to them both in cash and in kind.

RESULTS FOR ALL HOUSEHOLDS

The level of original income varies widely between households. Table A shows this and other income measures for quintile groups ranked by equivalised disposable income (the lowest quintile group

contains the 20 per cent of households with the lowest equivalised disposable incomes). In the lowest quintile group the average number of economically active people is 0.3 and hence the average original income is low (£1,280 per annum). In the highest quintile group, there are an average of 1.7 economically active people and average original income is £30,050. In the lowest quintile group, half of the households are retired (Table B) - defined as households where at least half the total gross income comes from retired people - and the majority of these have virtually no original income since the state retirement pension (including any graduated or additional pension) is a cash benefit.

Chart 2 illustrates the declining importance of cash benefits in gross income as income rises.

Chart 3 shows how the dispersion of incomes is reduced at each stage of the tax-benefit system, so that the average final income for each quintile group ranges from £5,200 to £21,400, a ratio of about 1:4 compared with the ratio for original incomes of about 1:23.

An alternative way to illustrate the extent of income redistribution is to examine how income shares are modified by the tax-benefit system (Table C). For example, households in the highest quintile group (when ranked by equivalised disposable income) receive around 50 per cent of all original income. After taking into account cash benefits, this same group's share falls to 42 per cent. At the other end of the scale, the share of the lowest quintile group rises from 2.0 per cent to 7.1 per cent. A further, but comparatively smaller, compression of the income distribution occurs at the stage of disposable income, but this is reversed after indirect taxes are taken into account. This table is calculated using equivalised

The composition of each quintile group of households, 1989

Total	100	100	100	100	100	100

1 This group is smaller than the category of "one parent families" because some of these families will be contained in larger household types.
2 With or without children

incomes, and hence 'final income' has not been included. The McClements equivalence scales, which were estimated using household spending patterns, are arguably inappropriate for equivalising non-spendable amounts of income eg benefits from education.

The Gini coefficient is the most widely used summary measure of the inequality of the distribution of income (see paragraph 40 of Appendix 2). It takes values between 0 and 100 per cent - the higher values indicating greater inequality. In this article, Gini coefficients are now calculated using equivalised incomes (using the same equivalence scale that is applied to equalise disposable income). The fall from 50 per cent to 36 per cent shown in Table C shows that cash benefits contribute the most to the reduction in income inequality.

Attention has already been drawn to the preponderance of retired households in the lower ranges of the distribution of original income; nearly half of the households in the bottom two quintile groups are retired (Table B). The income pattern of the retired is very different from that of households whose head is of working age, as is their expenditure pattern (which is reflected in their indirect tax payments). For this reason in the detailed examination of each stage of the tax-benefit system which follows, retired and non-retired households are analysed separately.

RESULTS FOR NON-RETIRED HOUSEHOLDS

Original income

The distribution of original income amongst non-retired households is more equal than among all households, ranging from an average of £3,260 per annum in the lowest quintile group to £32,660 in the highest (Table D), a ratio of 1:10 compared to the ratio of 1:23 for the distribution over all households. There is a relatively strong relationship between the original income of a household and the number of economically active people it contains and Table K (at the end of this section) gives a breakdown by the number of economically active people per household.

CHART 2

Sources of gross income, by quintile groups of equivalised disposable income, 1989

The effects of taxes and benefits on quintile groups¹ of households, 1989

TABLE C

1 This is a measure of the dispersion of each definition of income. Unlike the percentage shares analysis where the household incomes are ranked only once, the Gini coefficient calculation needs a separate ranking for each income definition. For example, the coefficient for original income is produced by first equivalising the original income of all the households, then this distribution is ranked and this ranked distribution is used to calculate the coefficient.

TABLE D

2 Children are defined as persons aged under 16 or aged between 16 and 18, unmarried and receiving non-advanced further education.

Average value of cash benefits for each quintile group of NON-RETIRED households, 1989

Total	15.1	19.2	20.3	21.6	21.9	20.7

1 After tax relief at source on mortgage interest and life assurance premiums.

benefit, is concentrated towards the bottom of the income distribution, in proportion to the number of children per household (Table D). The other non-contributory benefits are mainly income-related, in particular Income Support (formerly Supplementary Benefit) and so payments are concentrated in the lowest quintile group, although the presence of some individuals with low incomes in high income households means that some payments are recorded further up the income distribution. Most contributory benefits, for which contribution records rather than income are the criteria for payment, are highest for the second quintile group. On average, cash benefits formed almost 10 per cent of the gross income of non-retired households: their payment resulted in a significant reduction in income inequality.

Income tax, NI Contributions and domestic rates

Both income tax payments and employees' National Insurance contributions are closely related to the size of original income. The payments by households of employees' National Insurance contributions in particular vary with the number of persons in employment and with their earnings. However, since National Insurance contributions are only levied on the first £325 of weekly earnings (the ceiling in operation during most of 1989), households in the top quintile group pay rather less in contributions as a percentage of gross income than the middle 60 per cent of households (Table F).

In 1989 over one-third of working age individuals had insufficient income to pay income tax, and marginal tax rates for taxpayers were 25 per cent or 40 per cent. The analysis of households when ranked by equivalised disposable income shows average rates were 4.5 per cent in the lowest quintile, rising steadily to 15.5 per cent in the top quintile. This pattern arises chiefly because the quintile groups are based on (after tax) equivalised disposable income, which means that even the lowest quintile is shown as paying some income tax. Additional reasons are the grouping together of sizeable and diverse populations of individuals into quintile groups of households, and the expression of tax as a proportion of gross (rather than taxable) income.

Domestic rates (which used to be treated in these articles as an indirect tax) are included here with income tax and NICs on the grounds that this is the appropriate treatment for the community charge which succeeded the rates. Rate rebates (treated as a cash benefit) were an integral part of the domestic rates regime, designed to attenuate the regressive impact of rates at the lower end of the income distribution. The treatment of rates in Table F is thus unusual, and overstates their regressive impact.

Indirect taxes

In total, indirect taxes expressed as a proportion of disposable income fall as disposable income rises (upper part of Table G), ranging from 29 per cent in the bottom quintile group to 16 per cent in the highest, though the highest quintile pay most in indirect taxes in absolute terms. However, individual taxes have different effects.

VAT, tobacco duty, beer duty and intermediate taxes (see box below) all fall as a percentage of disposable income as income rises. The fall in tobacco duty payments as a percentage of income is particularly marked. For expenditure items relating to motoring (ie car tax and duty on hydrocarbon oils), the tax as a proportion of income is similar for the bottom four quintile groups but much lower for the top group.

Indirect taxes as a percentage of (a) disposable income and (b) expenditure on goods and services for each quintile group of NON-RETIRED households, 1989

TABLE G

1 Excludes savings, investments, superannuation contributions, and mortgage payments but includes imputed rent of owner occupiers (see paragraph 28 of Appendix 2 for the full definition of expenditure).

INTERMEDIATE TAXES

Some indirect taxes, such as VAT and excise duties on petrol, alcohol, tobacco, etc have a direct effect on the final price of goods and services. However, the producers of these goods and services also incur costs such as employers' National Insurance contributions, non-domestic rates, and duty on hydrocarbon oils, part of which they may pass on to households in the price of their products. These are called intermediate taxes.

The incidence assumptions used for these taxes are more difficult and contentious than those used for other taxes, so the figures must be regarded as very rough estimates.

Although some indirect taxes are less regressive than others, Table G (upper part) shows that the impact of virtually all the indirect taxes declines for the top quintile group compared with the fourth quintile group. This is so partly because higher income households tend to save a larger proportion of their income than households with smaller incomes.

The estimates of households' payments of indirect taxes are derived from figures for their expenditure recorded in the FES. Because the

data on expenditure and incomes in the FES are compiled in different ways, they may not be fully compatible (see Appendix 2, paragraph 5).

Thus, Table G also shows estimates of indirect tax payments expressed as a percentage of expenditure (in the lower part of the table), as these figures are fully consistent. Indirect taxes in total form a virtually constant proportion of expenditure on goods and services over all income groups. However, VAT payments actually rise as a proportion of expenditure as income goes up. This is largely due to the effects of zero-rating some items such as food and domestic fuel and power, which make up a higher proportion of the spending of the lower income groups. The apparent paradox of indirect taxes being regressive against disposable income but neutral against expenditure can be explained, at least in part, as follows: as income rises, there is a tendency for an increasing proportion of disposable income not to be spent on goods and services but to be channelled into savings, investments and mortgage payments.

Benefits in kind

Government current expenditure in providing certain goods and services to households either free at the time of use or at subsidised prices is converted by imputation into the equivalent of an income flow to individual households in order to arrive at final income. The largest two items for which such imputations are made are the health and education services, which together accounted for 23.3 per cent of total general government expenditure in 1989. Other items for

which imputations are made are school meals and welfare milk, the housing subsidy and travel subsidies, together accounting for a further 1.6 per cent of general government expenditure.

Education benefit to individual households is imputed by reference to the number of pupils and students in the state sector in the households (students living away from home are not included as part of their parents' household), and to the type of education they are receiving, though no allowance is made for differing costs between local authorities. No benefit is allocated for pupils at private schools. The bottom quintile group contains the highest number of children and consequently the highest number of those in full-time education (Table D). This is the main reason for this quintile group being allocated the highest average imputed benefit (Table H). Another important factor is the presence of the majority of student-only households, for whom the costs of education are greatest. Similarly the impact of expenditure on school meals and welfare milk is greatest in the lower income groups where children are more likely to take school meals and have them provided free of charge.

Data are available on the average cost to the Exchequer of providing the various types of health care - hospital inpatient/outpatient care, GP consultations, dental services etc - and it is possible to estimate the use made of each service on average by individuals of different ages and sex. Using this information, an imputed benefit from the state health service can be allocated to each individual in the FES sample; no allowance is made for the use of private health care services. These benefits are then aggregated for members of the household to yield figures on a household basis, so that not only the sex and age composition but also the size of the household determines the attribution of health service benefits.

Age and sex are by no means the only possible determinants on which to base the allocation, but age is certainly a very important factor. Data availability also limits the choice of determinants - the FES collects little information on health or use of health services. Table H indicates that these benefits decline steadily as income goes up.

Average value of benefits in kind for each quintile group of NON-RETIRED households, 1989

TABLE H

Benefits in kind as a percentage of post-tax income							
..	..	80	33	20	12	6	19

1 Does not include tax relief at source on mortgage payments. These are taken into account in the income tax payments shown in Table F.

Housing subsidy is the sum of Exchequer subsidy and local authority determined rate fund contributions to the housing revenue account. Thus housing subsidy as defined here has been spread between public sector tenants, and since such households tend to be concentrated in the lower half of the income distribution this is where the subsidy is highest. In these articles, tax relief on mortgage interest is treated as an adjustment to income tax, not as part of the housing subsidy analysed in Table H.

Percentage shares of total household income and Gini coefficients⁽¹⁾ for NON-RETIRED households, 1989

TABLE J

Percentage shares of total equivalised income for NON-RETIRED households ranked by equivalised disposable income				
	Original income	Gross income	Disposable income	Post-tax income
Quintile group				
Bottom ..	3.6	7.0	7.5	6.5
2nd ..	12	13	13	12
3rd ..	17	17	17	17
4th ..	24	23	23	23
Top ..	43	40	39	42
All non-retired households	100	100	100	100
Decile group				
Bottom ..	1.0	2.8	3.0	2.4
Top ..	27	25	24	26
Gini coefficient (percent) ..	40	33	32	36

1 This is a measure of the dispersion of each definition of income. Unlike the percentage shares analysis where the household incomes are ranked only once, the Gini coefficient calculation needs a separate ranking for each income definition. For example, the coefficient for original income is produced by first equivalising the original income of all the households, then this distribution is ranked and this ranked distribution is used to calculate the coefficient.

Travel subsidies cover the passenger element of the grants made to various public operations covering both buses and railways. The use of public transport by non-retired households is partly related to the need to travel to work and thus to the number of economically active people in a household and so the combined effect of these travel subsidies increases over the income distribution.

Table H shows that taken together the absolute values of these benefits in kind clearly decline as household income increases. As a proportion of post-tax income, benefits decrease from 80 per cent in the lowest quintile group to 6 per cent in the highest quintile group, indicating that this expenditure contributes to the reduction in income inequality.

Summary

The overall effect of the various stages of the tax-benefits system on non-retired households is summarised in Table J. Households in the highest quintile group receive 43 per cent of all (equivalised) original income, compared with 3.6 per cent received by the lowest quintile group. However, after direct taxes and benefits are taken into account, the share of the lowest quintile group rises to 7.5 per

Average incomes, taxes and benefits by the number of economically active people per NON-RETIRED household, 1989

1 Economically active people comprise employees, the self employed and others not in employment but who are seeking or intending, when able, to seek work.

2 These are income tax (which is after tax relief at source on mortgage interest and life assurance premiums) and gross domestic rates/Community charge.

cent and that of the highest falls to 39 per cent. Cash benefits are the major factor underlying these changes, causing the Gini coefficient to fall from 40 per cent based on original income to 33 per cent based on gross income. Income tax, employees' National Insurance contributions and rates produced a further reduction in inequality, but payment of indirect taxes increases inequality.

Economic activity

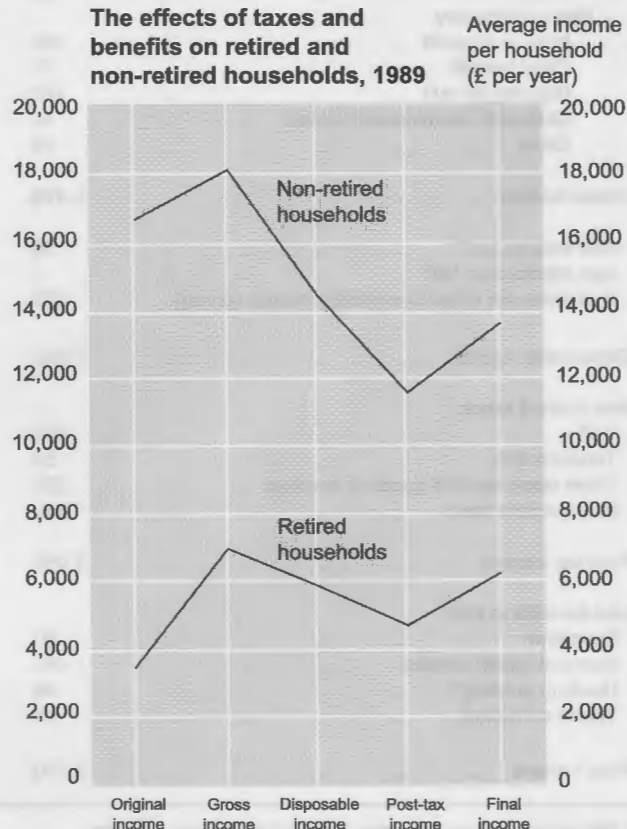

As already mentioned, the size of original income is largely determined by the number of economically active people in the household - even though someone may be defined as economically active if they have been out of work for up to a year as long as they are seeking work. This relationship between income and economic activity amongst non-retired households is explored further in Table K, in which households are classified according to the number of economically active people they contain.

Original income ranges from an average of £1,410 per annum in households where there are no economically active people to an average of £27,100 for households where there are three or more. Cash benefits are concentrated in households where no-one is economically active and here they form 75 per cent of gross income; but they remain important, at 11 per cent of gross income, for those where one household member is economically active. This latter group will contain a number of households where no-one is currently in work.

Not only does average original income differ widely between the four households groups in Table K, but there is also a considerable difference in the degree of variation of income within the groups. As measured by the Gini coefficient, variability in original income is

CHART 4

The effects of taxes and benefits on retired and non-retired households, 1989

very high amongst households where no-one is economically active but where two or more persons are economically active the variability is considerably less. Equally, the tax-benefit system has the effect of substantially reducing inequality between the different types of households within the economically inactive group. This results largely from the diverse nature of the economically inactive group, which ranges from single parents with young children, single full-time students, the disabled, and households where no member has been able to find work during the 12 months prior to interview, to a small number of households where income from other sources such as investments means that they have no need to work.

RESULTS FOR RETIRED HOUSEHOLDS

Retired households have quite distinct income and expenditure patterns and so the tax-benefit system affects them in a different way from non-retired households (Table L). Few retired households

have substantial original income; those who do are concentrated in the top two quintile groups and are receiving occupational pensions. The majority of retired households are dependent on cash benefits, in the form of state retirement pensions and income-related benefits such as Housing Benefits and Income Support to pensioners.

Cash benefits form a very high proportion of gross income for all but the better-off retired households. However, unlike non-retired households, the bulk of these cash benefits are paid from the National Insurance Fund into which the recipients will have made contributions throughout their working lives.

People over pensionable age do not pay National Insurance contributions so the small payments recorded are made by non-retired people living in households defined as retired (see Appendix 2 paragraph 7 for details of definition). All households except those in the highest quintile group of retired households pay very little

1 After tax relief at source on mortgage interest and life assurance premiums.

2 Does not include tax relief at source on mortgage payments, which is included in the income tax payments shown above.

income tax, because their income is unlikely to exceed their tax allowances unless they have significant income from investments or occupational pensions in addition to their state retirement pension. The largest indirect tax payment made by retired households is VAT, and the top quintile group pays more than twice as much as the average for all retired households.

Retired households derive significant benefits from health services and, to a lesser extent, the housing subsidy and travel subsidies, though of course virtually none from the education service. Health benefit is spread fairly evenly within the group of retired households, as a result primarily of the attribution method used, but housing subsidy is substantially higher for the middle three quintile groups since they have the highest concentration of public sector tenants. The benefits received by retired households from travel subsidies are mainly for bus travel, particularly in the form of concessionary fares, passes, etc, for senior citizens, and since these are not usually means-tested but depend instead on what sort of scheme is being operated by their local authority, there is no particular relationship with income.

Table M shows the extent to which income inequality amongst retired households is reduced by the tax-benefit system. Cash benefits play by far the largest part in bringing about this reduction and income tax payments make a further, though much smaller, contribution. Payments of indirect taxes result in an increase in inequality.

A comparison of Table M with Table J shows that although the distribution of original income amongst retired households is much more unequal than that within the non-retired household group, the distribution of post-tax income is more equal amongst the retired than amongst the non-retired. Chart 4 illustrates the different impact which the tax-benefits system has on retired and non-retired households.

METHODOLOGY AND DEFINITIONS

The allocation of government expenditure and its financing

1. There are considerable difficulties in moving from the aggregates of government expenditure and financing published in the United Kingdom National Accounts - the CSO Blue Book - to apportioning taxes and benefits to individual households. We can obtain information about the types of household that receive cash benefits and pay direct taxes through surveys such as the Family Expenditure Survey (FES). From the replies respondents give to questions on their expenditure we can impute their payments of indirect taxes, and from information they supply about such factors as their ages and number of children in the household we can estimate the average costs of providing them with social services, such as health and education. But there are other kinds of financing, such as corporation tax and government receipts from public corporations: no attempt is made in this analysis to apportion them to households because it would be too difficult. Similarly, there are other items of government expenditure, such as capital expenditure and expenditure on defence and on the maintenance of law and order, for which there is no clear conceptual basis for allocation, or for which we do not in any event have sufficient information to make an allocation. In all, 66 per cent of government financing (including the Borrowing Requirement) and 50 per cent of expenditure are allocated to households in this analysis.

Family Expenditure Survey (FES)

2. The estimates in this article are based mainly on data derived from the FES. The FES is an annual survey of the expenditure and income of private households. People living in hotels, lodging houses, and in institutions such as old peoples' homes are excluded. Each person aged 16 and over keeps a full record of payments made during 14 consecutive days and answers questions about hire purchase and other payments. The respondents also give detailed information, where appropriate, about income (including cash benefits received from the state) and payments of income tax. Information on age, occupation, education received, family composition and housing tenure is also obtained. The survey covers the whole 12 month period.

3. One of the main purposes of the FES is to produce information on household expenditure patterns which is used to derive the weights for the index of retail prices. The survey is conducted by the Office of Population Censuses and Surveys on behalf of the Central Statistical Office who analyse and report on it (prior to July 1989, the FES was the responsibility of the Department of Employment). The Family Expenditure Survey Report for 1989, containing detailed data on household characteristics, income, and expenditure, was published in November 1990. Details of the survey method are set out in 'The Family Expenditure Survey Handbook' by W F F Kemsley, R U Redpath and M Holmes. Both are published by Her Majesty's Stationery Office.

4. The number of households in the United Kingdom responding to the FES in 1989 was 7,410 (about 1 in every 3,000 households). The response rate in Great Britain was 73 per cent: the FES in Northern Ireland is done as a separate exercise to the rest of UK, with a larger sampling fraction, and only a proportion of these cases go into the UK analysis. To count as a co-operating household, all members aged 16 and over must fill in the diaries for both weeks and give full

details of income etc. The available evidence suggest that older households, households where the head is self-employed, those without children and higher income households, are less likely to co-operate than others (see 'Family Expenditure Survey: a second study of differential response, comparing Census characteristics of FES respondents and non-respondents' by Bob Redpath, *Statistical News* No 72 February 1986 HMSO). In addition response in Greater London is noticeably lower than in other areas. However, at present, the results in this article are based on the responses of those households which actually co-operated in the survey and they are not reweighted. This means that some of the figures differ from those produced by other surveys such as the Survey of Personal Incomes from the Inland Revenue.

5. The FES is designed primarily as a survey of expenditure on goods and services by households. It has been developed to gather information about the income of household members, and is an important and detailed source of income data. However, no information is collected that would enable a balance sheet of income and expenditure to be drawn up for a household over any particular period. Much expenditure relates to the two-week period after the interview, whereas many income components refer to a much longer period (eg investment income over the previous 12 months). FES income does not include proceeds from the sale of assets (eg a car) or windfalls such as legacies. But recorded expenditure might reflect these items, as well as the effects of living off savings, using capital or borrowing money. Hence, there is no reason why income and expenditure should balance either for an individual household or even averaged over a group of households. Indeed, measured expenditure substantially exceeds measured income for the bottom decile groups of households. Moreover, the difference between income and expenditure is not necessarily a measure of savings or dis-savings.

Unit of analysis

6. The basic unit of analysis in the article is the household, and not the family, individual or benefit unit. A household is defined in the FES as comprising people who live at the same address and who share common catering for at least one meal a day. Spending on many items, particularly on food, housing, fuel and light, is largely joint spending by the members of the household. Without further information or assumptions it is difficult to apportion indirect taxes between individuals or other sub-divisions of households.

7. In classifying the households into various types, a **child** (ie a dependant) is defined as:

either aged under 16

or aged 16, 17 or 18 not married, and receiving full-time non-advanced further education.

[The definition used in the pre-1987 articles was a person aged under 16].

Most of the 'extra' adults in households with at least three adults are sons or daughters of the head of household rather than retired people.

8. A **retired household** is defined as one where the combined income of retired members amounts to at least half the total gross income of the household, where a retired person is defined as anyone

who describes themselves as 'retired' or anyone over minimum NI pension age describing themselves as 'unoccupied' or 'sick or injured but not intending to seek work'.

9. By no means all retired people are in retired households: about one in five households comprising three or more adults contain retired people, for example, and households comprising one retired and one non-retired adult are often classified as non-retired.

10. The sample households have been classified according to their compositions at the time of the interview. This classification is sensible for the vast majority of households, but it can be misleading for the very small number of cases (32 in 1989) where a spouse is absent from the household at the time of interview. The absent spouse may well be working away from home (eg on an oil rig), or living separately - but contributing financially to the household's upkeep. These contributions would be picked up as part of the household's original income. Also, it is likely that some households will have changed their composition during the year.

11. Economically active people comprise employees, the self-employed and others not in employment but who are seeking or intending, when able, to seek work. In 1982 there were changes in the FES in the definition relating to economic activity. The effect of these changes is to exclude all those out of employment for more than a year rather than five years. This exclusion applies regardless of the fact that they may still describe themselves as seeking work. Also excluded are those who have not been in paid employment since leaving full-time education unless they have worked within the previous year; certain of the part-time self-employed with very small incomes: and those whose only economic activity is working as mail-order agents or baby-sitters.

Income: redistributive stages

12. Stage one:

Original income plus cash benefits = Gross income.

Stage two:

Gross income minus income tax, employees' National Insurance contributions and domestic rates = Disposable income.

Stage three:

Disposable income minus indirect taxes = Post-tax income.

Stage four:

Post-tax income plus 'benefits in kind' = Final income.

13. The starting point of the analysis is original **income**. This is the annual income in cash of all members of the household before the deduction of taxes or the addition of any state benefits. It includes income from employment, self-employment, investment income, occupational pensions and annuities. Employment income is based on the last payment received before the interview or, where different, the amount usually received. Allowance is made for any periods of absence from work through sickness and unemployment in the preceding 12 months, and for bonuses. Income from self-employment is recorded in the FES for a past period. This is brought up to current levels using the average earnings index. Income from interest, dividends and rent is taken as the amount received in the 12 months before the interview. Income from occupational pensions is based on the last payment received.

14. About 99 per cent of original income comes from earnings, occupational pensions (including annuities) and investment income. The tiny bit remaining comes from a variety of sources: trade union

benefits, income of children under 16, private scholarships, earnings as a mail order agent or babysitter, regular allowance from a non-spouse, allowance from an absent spouse and the imputed value of rent-free accommodation. Households living in rent-free dwellings are each assigned an imputed income based on the rateable value of the dwelling. This is counted as employment income if the tenancy depends on the job.

15. The next stage of the analysis is to add cash benefits to original income to obtain **gross income**. This is slightly different to the 'gross normal weekly income' used in the FES Report, mainly because it excludes the imputed rent of owner-occupiers. Cash benefits are:

Contributory:

Retirement pension and Christmas bonus, unemployment benefits, sickness and industrial injury benefit, statutory sick pay, invalidity pension and allowance, industrial injury disablement benefits, widows' benefits, and statutory maternity pay.

Non-contributory:

Supplementary benefit, child benefit, housing benefit, attendance allowance, mobility allowance, war pensions, severe disablement allowance, family income supplement, old persons pension, government training scheme allowances (YTS etc), student maintenance awards, maternity grant.

16. Statutory Sick Pay and Statutory Maternity Pay are classified as cash benefits even though they are paid through the employer.

17. Income from short-term benefits is taken as the product of the last weekly payment and the number of weeks the benefit was received in the 12 months prior to interview. Income from long-term benefits, and from housing benefit, is based on current rates.

18. Income tax, domestic rates and employees' and self-employed contributions to National Insurance and National Health services are then deducted to give **disposable income**. Taxes on capital, such as capital gains tax and inheritance tax, are not included in these deductions because there is no clear conceptual basis for doing so, and the relevant data is not available from the FES.

19. The figures for domestic rates include, as well as local authority rates, charges made by water authorities for water, environmental and sewerage services. Rates are shown in full with any rebates given in housing benefit.

[In pre-1987 articles, domestic rates were included in the 'indirect' tax category. They are now deducted in the derivation of disposable income in anticipation of their replacement by the community charge from 1989. The National Accounts system, which strongly influences this article, will show the community charge as a deduction before disposable income is produced].

20. The tax estimates are based on the amount deducted from the last payments of employment income and pensions, and on the amount paid in the last 12 months in respect of income from self-employment, interest, dividends and rent. The income tax payments recorded will therefore take account of a household's tax allowances, with the exception of tax relief obtained in this way 'at source'. In 1989 there were two types of tax relief obtained in this way: mortgage interest relief and life assurance premium relief. Where households are eligible for these reliefs imputations are made and deducted from recorded income tax payments. In the case of mortgage interest relief obtained through the MIRAS scheme, which was introduced

in April 1983, these imputations are based on the interest component of the latest mortgage repayment.

21. The next step is to deduct indirect taxes to give **post-tax income**. Indirect tax on final consumer goods and services include:

- Duties on beer, wines, spirits, tobacco, oil, betting, etc
- Value Added Tax (VAT)
- Customs (import) duties
- Car tax
- Motor vehicle duties
- Driving licenses
- Stamp duties
- Gas levy

22. Taxes levied on final goods and services are assumed to be fully incident on the consumer, and can be imputed from a household's FES expenditure record. For example, the amount of VAT which is paid by the household is calculated from the household's total expenditure on goods and services subject to VAT.

23. VAT and car tax affect the prices of secondhand cars and are therefore assumed to be incident on the purchasers of such cars as well as on the purchasers of new cars. In allocating taxes, expenditures recorded in the FES on alcoholic drink, tobacco, ice cream, soft drinks and confectionery are grossed up to allow for the known under-recording of these items in the sample. The true expenditure in each case is assumed to be proportional to the recorded expenditure. This approach has its drawbacks because there is some evidence to suggest that heavy drinkers, for example, are not picked up by the FES.

24. The incidence of stamp duty on house purchase on an owner-occupying household has been taken as the product of the hypothetical duty payable on buying their current dwelling (estimated from rateable values) and the probability of a household of that type moving in a given year (estimated from the General Household Survey).

25. Indirect taxes on intermediate goods and services are:

- Local authority rates on commercial and industrial property
- Motor vehicle duties
- Duties on hydrocarbon oils
- Employers' contributions to National Insurance, the National Health Service, the industrial injuries fund and the redundancy payments scheme
- Customs (import) duties
- Stamp duties
- VAT

26. These are taxes that fall on goods and services purchased by industry. Only the elements attributable to the production of subsequent goods and services for final consumption by the UK personal sector are allocated in the article, being assumed to be fully shifted to the consumer. Their allocations between different categories of consumers' expenditure are based on the relation between intermediate production and final consumption using estimated input-output techniques. This process is not an exact science, and many assumptions have to be made. Some analyses, eg that by Dilnot, Kay and Keen 'Allocating Taxes to Households: A Methodology', suggest that the taxes could be progressive rather than regressive if one were to use different incidence assumptions.

27. In discussing the incidence of indirect taxes, we have used the terms '**progressive**' and '**regressive**' to mean taking an increasing or decreasing proportion of income as income rises. The degree to

which a tax is progressive or regressive is strongly affected by the definition of income which the tax is compared with. For example, if indirect taxes were to be compared with gross income (rather than disposable income as in this article), they would appear much more regressive than shown in Table G of this article.

28. For Table G of the main article, we have constructed a measure of expenditure on goods and services which is similar to that used in the Consumers' Expenditure part of the National Accounts. Savings, investments, superannuation contributions and mortgage payments are excluded as well as rates/community charge payments. Imputed rent 'payments' for owner occupiers are included because rent payments are included for households renting their accommodation. We have included payments for house repairs and improvements because VAT is charged on these items. The expenditures on alcohol, tobacco and confectionery have been grossed up to correspond to the grossed-up indirect tax amounts described in paragraph 23 above.

29. Finally, we add those notional benefits in kind provided to households by government for which there is a reasonable basis for allocation to households, to obtain **final income**. Benefits in kind are:

- State education
- School meals and welfare milk
- National Health service
- Housing subsidy
- Railway travel subsidy
- Bus travel subsidy (including concessionary fares schemes)

30. Education benefit is estimated by the Department of Education and Science as the cost per pupil or student in special schools, primary and secondary schools, universities, and other further education establishments. The value of the benefits attributed to a household depends on the number of people in the household recorded in the FES as receiving each kind of state education (students away from the household are excluded). No benefit is allocated for pupils attending private schools.

31. The value of school meals and other welfare foods is based on their costs to the public authorities. Any payment by the individual household is subtracted to arrive at a net contribution.

32. Each individual in the FES is allocated a benefit from the National Health Service according to the estimated average use made of the various types of health service by people of the same age and sex, and according to the total cost of providing those services. The benefit from maternity services is assigned separately to those households containing children under the age of 12 months. No allowance is made for the use of private health care services.

33. In this article public sector tenants are defined to include the tenants of local authorities, New Town Corporations, the Scottish Special Housing Association (SSHA), Northern Ireland Housing Executive (NIHE) and housing associations. The total housing subsidy includes the contribution from rate funds and from central government to the housing revenue accounts of local authorities: and grants paid to the New Town Corporations, the SSHA, the NIHE and housing associations. Within Greater London, the rest of England, Wales, Scotland and Northern Ireland each public sector tenant has been allocated a share of the region's total relevant subsidy based on the gross rateable value of this dwelling. Housing subsidy does not include mortgage interest tax relief, rent rebates and allowances or rate rebates included in housing benefit (see paragraphs 15 and 19 respectively).

34. The rail travel subsidies allocated are those to British Rail passenger operations and the London Underground. The subsidy to London and South East services is allocated to households living in the area and subsidies to provincial services to households living outside the South East, in proportion to households' expenditure on rail fares as recorded in the FES. A single allocation of the subsidy to inter-city services was made by dividing that subsidy between all households in proportion to their recorded expenditure on rail fares. In making both these allocations allowances are made for the use of rail travel by the business sector, tourists and the institutional part of the personal sector.

35. In this article, bus travel subsidy covers both the cost of concessionary travel schemes for senior citizens and others, and subsidies to operators. Separate allocations are made for Greater London, the other metropolitan areas and the rest of the United Kingdom. The subsidy is divided between households according to recorded expenditure on bus travel and the types of concessionary passes held.

36. We must emphasise that the analysis in this article provides only a very rough guide to the kinds of household which benefit from government expenditure, and by how much, and to those which finance it. Apart from the fact that large parts of expenditure and receipts are not allocated, the criteria used both to allocate taxes and to value and apportion benefits to individual households could be regarded as too simplistic. For example, the lack of data forces us to assume that the incidence of direct taxes falls on the individual from whose income the tax is deducted. This implies that the benefit of tax relief for mortgage interest, for example, accrues directly to the taxpayer rather than to some other party, for instance, the vendor of the land. It also implies that the working population is not able to pass the cost of the direct tax back to employers through lower profits, or to consumers through higher prices. And, in allocating indirect taxes we assume that the part of the tax falling on consumers' expenditure is borne by the households which buy the item or the service taxed, whereas in reality the incidence of the tax is spread by pricing policies and probably falls in varying proportions on the producers of a good or service, on their employees, on the buyer, and on the producers and consumers of other goods and services. Another example is that we know only an estimate of the total financial cost of providing benefits such as education, and so we have to treat that cost as if it measured the benefit which accrues to recipients of the service. In fact, the value the recipients themselves place on the service may be very different to the cost of providing it: moreover, there may be households in the community, other than the immediate beneficiaries, who receive a benefit indirectly from the general provision of the service.

Equivalence scale

37. The equivalence scale used in this analysis is the *McClements scale* (before housing costs are deducted). The scales (separate ones for before and after housing costs) were developed by Dr L D McClements at the Department of Health and Social Security (DHSS) in the mid-seventies, based on expenditure data from the 1971 and 1972 FES. They are based on the assumption that it is possible to estimate equivalence scales from people's spending behaviour as recorded in the FES without making any specific assumption about the criteria for equivalence. These scales are in regular use, though it is recognised that they are based on what is now rather old expenditure data and that it might be desirable to update them. The scales are regarded as plausible and they are well within the range of equivalence scales developed at different times in a number of countries. Hence their use is fully justified for broad statistical standardisation pending any re-calculation.

38. The equivalence values are given below:

Type of household member	Equivalence value
<u>a. married head of household</u>	
(ie a married couple of 2 adults)	1.00
1st additional adult	0.42
2nd (or more) additional adult	0.36 (per adult)
<u>b. single head of household</u>	
(ie 1 adult)	0.61
1st additional adult	0.46
2nd additional adult	0.42
3rd (or more) additional adult	0.36 (per adult)
<u>c. Child aged:</u>	
16-18	0.36
13-15	0.27
11-12	0.25
8-10	0.23
5-7	0.21
2-4	0.18
Under 2	0.09

The values for each household member are added together to give the total equivalence number for that household. This number is then divided into the disposable income for that household to give **equivalised disposable income**. For example, a household has a married couple with 2 children (aged 6 and 9) plus one adult lodger. The household's equivalence number is 1.0 + 0.21 + 0.23 + 0.42 = 1.86. The household's disposable income is £20,000, and so its equivalised disposable income is £10,753 (=£20,000/1.86).

39. This quantity is used to produce the single ranking used in all the tables in this article (apart from the Gini coefficients which have to be ranked afresh for each different definition of income). [In pre-1987 articles, three types of ranking were used: the main one was using original income but gross income and disposable income were also used. In addition, the tables showing income shares were re-ranked for each separate income measure]. It is important to note that most monetary values shown in the article are ordinary (ie un-equivalised) £ a year, not equivalised £ a year. Where equivalised £ a year do appear (eg the quintile points in Table 3 of Appendix 1), they are shown in *italics*.

Gini coefficient

40. The Gini coefficient is the most widely used summary measure of the degree of inequality in an income distribution. It can more easily be understood by considering a Lorenz curve of the income distribution, (see Diagram B) ie a graph of the cumulative income share against the cumulative share of households. The curve representing complete equality of income is thus a diagonal line while complete inequality (with only one recipient of income) is represented by a curve comprising the horizontal axis and the right-hand vertical axis (see Diagram A). The area between the Lorenz curve and the diagonal line of complete equality, as a proportion of the triangular area between the curves of complete equality and inequality, gives the value of the Gini coefficient. Thus a distribution of perfectly equal incomes has a Gini coefficient of zero; as inequality

Diagram A

Diagram B

increases (and the Lorenz curve bellies out), so does the Gini coefficient until, with complete inequality, it reaches its maximum value of 1 (or 100 per cent).

41. To calculate the Gini coefficient for an income distribution, the first step is to rank that distribution in ascending order. All the Gini coefficients shown in this article are based on distributions of equivalised income eg the coefficient for original income is calculated after dividing the original income for all the households by their appropriate equivalence values.

[In pre-1987 articles, no such equivalisation was used].

42. Strictly speaking, one could argue that the equivalence scales used here are only applicable to disposable income because this is the only income measure relating directly to spending power. Since the scales are often applied, in practice, to other income measures, we are content to use them to equalise original, gross and post-tax income for the purpose of producing Gini coefficients (and in the tables giving percentage shares of total income). However, we do not think it is appropriate to equalise the final income measure because this contains notional income from benefits in kind (eg state education): the equivalence scales used in this article are based on actual household spending and do not, therefore, apply to such items as notional income.

Sampling errors and reliability

43. As the FES is a sample survey, data from it will differ in varying degrees from those of all households in the UK. The degree of difference will depend on how widely particular categories of income and expenditure vary between households. This 'sampling error' is smallest in relation to, say, the average expenditure of large groups of households on items purchased frequently (when spending does not vary greatly between households). Conversely, it is largest for small groups of households, and for items or services purchased infrequently (for which expenditure varies considerably between households). A broad numerical measure of the amount of variability is provided by the quantity known as the standard error.

44. It is difficult to calculate these standard errors exactly because of the multi-stage design of the FES, but we have made a good approximation by combining the simple random formula with the

appropriate design factor from the FES analysis. [The design factor is the ratio of the standard error using the detailed formula that takes account of the full complexity of the sample design to the standard error using the simple random sample formula]. The most appropriate design factor from the FES work is for 'gross normal weekly household income'. The standard error of the mean for N households in Table 1 is given by:

$$(\text{design factor}) * S/\sqrt{N}$$

where the design factor is 1.22 for 1989, and S^2 is the estimate of the population variance.

This simple formula is applicable to a complete group of households, but for quintile or decile groups a more complex formula is required (see paragraph 46).

45. The standard errors can be used to give an idea of the reliability of a mean by quoting a confidence interval of the form:

$$\text{estimate of mean} \pm (1.96 * \text{standard error})$$

where the factor 1.96 corresponds to the 95% confidence interval.

For example: the mean disposable income for all households is £12,039 (see Table 3 in Appendix 1), and its standard error is £140 (from Table 1 below). So the confidence interval for the population value is £12,039 \pm £274 ie about (£11,750 to £12,300). It is very likely that the mean disposable income for the whole population (ie all UK private households) will lie in this range.

46. The standard errors for the household types are larger than for the whole sample, mainly because the sample sizes concerned are smaller. For quintile groups of given household types, the sample sizes are of course smaller still, which would tend to increase sampling variability. On the other hand, the income values are by definition in a narrower range which would tend to reduce the sampling error. Precise estimates of standard errors for averages for quintile groups are complicated to produce. As well as the variability of the observations between the quintile points, we should also take account of the randomness which exists because the sample quintile points are themselves subject to random variation. We have used a formula for the asymptotic variance of a 'randomly trimmed' mean.

This formula gives a good approximation where the total sample size is around 1,000 (when the variance is under-estimated by about 2 per cent on average), and a reasonable approximation for samples of 100-500 (when the variance is under-estimated by about 5 per cent on average). The formula for the variance of a mean (\bar{x}) calculated between two sample percentiles, Q_1 and Q_2 , corresponding to proportions p_1 and p_2 is:

$$\begin{aligned} & [n(p_2-p_1)]^{-1} * \\ & \{ S^2 \\ & + p_1(\bar{x}-Q_1)^2 \\ & + (1-p_2)(Q_2-\bar{x})^2 \\ & + [p_1(1-p_2)/(p_2-p_1)](Q_2-Q_1)^2 \} \end{aligned}$$

where S^2 = variance calculated from observations between Q_1 and Q_2 , and

n = total sample size.

The square root of this quantity is then multiplied by the design factor (as described in paragraph 44) to give the standard errors shown in the tables for quintile and decile groups.

47. The 'complex' standard errors for quintile and decile groups are quite a bit larger than the simple random sample estimates, as shown below:

Ratio of 'complex' standard error to simple random sample estimate for equivalised disposable income, 1989

Decile group		Quintile group	
Bottom	1.65	Bottom	1.78
2nd	4.45	2nd	3.91
3rd	5.75	3rd	4.46
4th	6.21	4th	3.97
5th	6.32	Top	1.42
6th	6.49	All	1.22
7th	6.16		
8th	5.49		
9th	4.43		
Top	1.42		
All	1.22		

For the 'all households' group the ratio merely reflects the fact that the simple random sample figure is multiplied by the design factor (1.22 in 1989) to produce the 'complex' standard error. For the middle quintile group, the quoted standard error is about four times larger than it would have been if we had merely used the simple random sample estimate. The quoted standard errors for the middle decile groups are about six times higher than the simple random sample estimates.

48. Table 2 gives standard errors for quintile groups of households within household type. The standard errors of the top quintile group are often much larger than for the other quintile groups. This is not surprising as, in general, any distribution of incomes has a long

positive tail. The standard errors for the top quintile groups of some household types are so large that it is doubtful whether the averages for these groups are reliable enough to be worth quoting in the tables in Appendix 1.

49. Another aspect of sampling errors and reliability is the variation from year to year. Table 3 gives the standard error of the mean (expressed as a percentage of the mean) for disposable income for the years from 1977 to 1989. The two groups with consistently high proportionate standard errors are one adult with children, and two adults with 3 or more children. Relatively small groups like these are more likely to be strongly influenced by unusually large income and expenditure values.

If the change between years were to be considered, then it is the standard error of the *difference* between years that is relevant. This is about 1.4 times the size of the standard error for a particular year (assuming the two standard errors are about the same) - because the variance of a difference between years equals the sum of the variances for those individual years.

50. This year, for the first time, we have produced estimates for the standard errors of **shares of total income** (shown in Table 1, Appendix 4). These standard errors have been calculated using the formula for the variance of a ratio, and the results are given in Table 4 below. For example, the top quintile group accounted for 41 per cent of total equivalised disposable income; the standard error of this estimate is 0.17 per cent, and the 95% confidence interval for the true value is (40.8, 41.4) per cent.

As the formula involves an approximation, the figures shown in Table 4 are likely to be under-estimates of the true position.

Previous articles

51. This article is the latest in an annual series. Earlier articles covering the years 1957 to 1986 (using the old methodology) were published in the following issues of *Economic Trends*: November 1962, February 1964, August 1966, February 1968, 1969, 1970, 1971, 1972, November 1972 and 1973, December 1974, February 1976, December 1976, February 1978, January 1979, 1980, 1981 and 1982, December 1982, November 1983, December 1984, December 1985, July 1986, November 1986, July 1987 and December 1988.

52. The results for 1987 (the first year of using the new methodology) were published in the May 1990 edition of *Economic Trends*, and the 1988 results appeared in the March 1991 edition. The latest three articles use a very different methodology to the earlier years, and hence are completely incompatible.

53. The results in all articles are intended to be free standing: they were not designed for direct comparison with other years except where some limited comparisons were made in the articles. Such comparisons are fraught with difficulty because of changes in definitions eg housing benefit in 1983. However, some broader measures like the Gini coefficients are relatively robust and will stand comparison with other years: this year's article gives such a comparison for the years 1977-1989. Enquiries should be addressed to Dave Westcott, Branch 3E, Central Statistical Office, Room 1936, Millbank Tower, Millbank, London SW1P 4QQ.

Corrigendum

54. The final column of Table G in last year's article (ie 1988 data on page 113 of March 1991 Economic Trends) contains some errors. The correct figures are given below:

TABLE G
Indirect taxes as a percentage of disposable income for non-retired households, 1988

Final column (All non-retired households)

<u>Percentages</u>	<u>Correct figure</u>	<u>As published</u>
VAT	8.0	8.6
Duty on beer	0.8	1.0
Duty on wines	0.8	0.8
Duty on tobacco	1.9	2.6
Duty on hydrocarbon oils	1.6	1.7
Car tax	1.1	1.1
Other taxes	1.4	1.4
Intermediate taxes	4.9	5.5
Total indirect taxes	20.5	22.8

Standard errors of the mean, 1989

TABLE 1 (Appendix 2)

				Standard error of the mean of the five income measures (£ per year)						
				Number in sample	Original income	Gross income	Disposable income		Post-tax income	Final income
							Unadjusted	Equivalised		
Household type/ Quantile group										
All households		7 410	190	178	140	114	125	131
Non-retired	5 484	225	213	169	140	155	160

Latest developments in the economy

Data available at 13 February 1992

DATA PUBLISHED BY CSO

Output

In the three months to November, the output of the production industries is provisionally estimated to have fallen by 0.6 per cent compared with the previous quarter, and by 1.4 per cent compared with the same period a year earlier. The provisional index of production figure for November is 105.9 (1985=100). The index covers the manufacturing and energy industries, and all figures are seasonally adjusted.

Manufacturing output in the three months to November was 1.2 per cent lower than in the previous three months, and 4.0 per cent down on the same period a year earlier. Within manufacturing, between the latest three month periods, the output of the metals industry fell by 1.6 per cent, chemicals rose by 2.3 per cent, engineering and allied industries fell by 2.6 per cent, "other manufacturing" fell by 0.8 per cent, "other minerals" fell by 1.0 per cent, textiles and clothing fell by 1.0 per cent, and food, drink and tobacco fell by 0.5 per cent.

The output of the energy sector was 0.9 per cent higher than in the preceding three months, and 6.4 per cent up on the same period a year earlier.

By market sector, between the latest three month periods, the output of the investment goods industries fell by 2.9 per cent, the output of the consumer goods industries fell by 0.2 per cent, and the output of the intermediate goods industries was unchanged.

Producer prices

The input price index for materials and fuel purchased by manufacturing industry fell by 1.1 per cent in the twelve months to January, following a fall of 1.2 per cent in the twelve months to December. Between December and January, the unadjusted index fell by 0.1 per cent, whereas the seasonally adjusted index rose by 0.7 per cent.

The increase over twelve months in the output price index for home sales of manufactured products was 4.5 per cent in January, compared with an increase of 4.9 per cent in December. The index rose by 0.7 per cent between December and January.

Retail prices

The general index of retail prices for 10 December was 135.7 (January 1987=100), an increase of 0.1 per cent on November and of 4.5 per cent since December 1990.

Between November and December there were increases in the prices of food, tobacco and household goods as well as a rise in housing costs. There were, however, a number of reductions, including a fall in petrol prices.

The tax and price index for December was 128.2 (January 1987=100), representing an increase of 4.0 per cent over the previous twelve months.

Retail sales

The final, seasonally adjusted estimate of retail sales volume in December was 119.3 (1985=100). In the three months to December sales were 0.1 per cent down on the previous quarter, but 0.3 per cent higher than the same period a year earlier. Sales by food retailers fell by 0.6 per cent compared with the previous three months, whereas those of specialist non-food retailers rose by 0.2 per cent, and those of mixed retail businesses rose by 0.5 per cent.

Based on non-seasonally adjusted data, retail sales value in current prices in December was 1 per cent higher than in December 1990.

Balance of payments

Information on visible trade in December and recent trends in invisibles imply a current account deficit of £0.4 billion, £0.2 billion less than that for November. In the latest three months the implied deficit was £1.6 billion, compared with £1.3 billion in the previous quarter.

The visible deficit in December was £0.7 billion, compared to £0.9 billion in November. In the three months to December the visible deficit was £2.5 billion, compared with £2.4 billion in the previous quarter.

In December the value of exports was £9.0 billion, 2.5 per cent higher than in November. In the three months to December, the value of exports was 0.5 per cent lower than in the previous three months, but 2.5 per cent higher than a year earlier. On a volume basis, excluding oil and the erratic items, exports in the three months to December were 2.5 per cent higher than in the previous three months, and 4 per cent higher than a year earlier.

Imports in December were valued at £9.6 billion, virtually unchanged from November. In the three months to December, the value of imports was unchanged from the previous quarter, and 0.5 per cent lower than a year earlier. Excluding oil and erratics, import volume in the three months to December was 1 per cent up on both the previous three months and the corresponding period a year earlier.

Estimates of invisibles are not available monthly. Based on recent trends and limited information on EC transfers, invisibles in December are projected to be in surplus by £0.3 billion, with a surplus on transactions by the private sector partly offset by a deficit on government transactions. Revisions to these projections can be substantial.

Public sector borrowing requirement

Provisional estimates put the public sector borrowing requirement at £1.2 billion in December. Privatisation proceeds in December amounted to £1.8 billion, from the first instalment of the November sale of BT holdings. The PSBR for the first nine months of 1991-92 was £10.5 billion compared with £2.1 billion in the same period last year. The PSBR excluding privatisation proceeds was £17.5 billion in the first nine months of 1991-92 compared with £5.8 billion in the same period last year.

DATA PUBLISHED BY OTHER DEPARTMENTS

Official reserves

The overall level of the UK's official reserves rose by \$460 million in January, bringing the end of January reserves to \$44,586 million (£24,874 million), compared with \$44,126 million (£23,625 million) at the end of December.

The underlying change in the reserves during January was a fall of \$336 million.

The underlying change excludes a number of factors which are included in the total change. Proceeds from the month's tender of UK ECU Treasury Bills amounted to \$1,166 million and maturing UK ECU Treasury Bills of \$1,165 million. The underlying change also excludes repayments of borrowing under the exchange cover scheme of \$12 million. There was no new borrowing under the exchange cover scheme.

Exchange rate

The sterling exchange rate index (1985=100) was 90.8 in January, compared with 91.2 in December.

Unemployment and vacancies

In January, the seasonally adjusted level of unemployment in the UK increased by 53,000 to 2.604 million, 9.2 per cent of the workforce. Over the past six months, unemployment has risen by 39,200 per month on average.

The stock of unfilled vacancies at jobcentres decreased by 1,900 to a seasonally adjusted 122,000 in the month to January. Over the three months to January, vacancies have increased on average by 6,200 a month.

Employment

The number of employees in employment in manufacturing industries in Great Britain stood at 4,635,000 in December, a fall of 18,000 since November. Employment has fallen by 334,000 in the year to December, compared with a fall of 129,000 in the previous year.

The UK workforce in employment (employees in employment, the self-employed, HM Forces and participants in work related government training programmes) stood at 25,938,000 in September, representing a fall of 234,000 in the quarter. Employment over the year to September 1991 fell by 875,000.

Earnings

The underlying increase in average weekly earnings in the year to November was about 7.5 per cent, the same as the increase in the year to October. The actual increase in the year to November, at 7.7 per cent, was above the underlying increase because of negative timing adjustments for bonuses.

In the production industries, the underlying increase in average weekly earnings in the year to December was about 8 per cent, a fall of 0.25 per cent on the increase in the year to November. Within this sector, the underlying increase in manufacturing industries in the year to December was about 7.75 per cent, 0.25 per cent below the increase in the year to November. The actual increases for production and manufacturing in the year to December were 7.8 per cent and 7.4 per cent respectively.

In the service industries, the underlying increase in average weekly earnings in the year to November was about 7.25 per cent, the same as the increase in the year to October. The actual increase in the service industries was 7.8 per cent.

Productivity

Manufacturing output per head in the three months to November was about 0.2 per cent higher than in the three months ending August, and 2.7 per cent higher than in the same period a year earlier. Output per head in the whole economy in the third quarter of 1991 was about 0.9 per cent higher than in the previous quarter, and about 0.6 per cent higher than in the corresponding quarter a year earlier.

Unit wage and salary costs

In the three months to November, wages and salaries per unit of output in manufacturing were 5.0 per cent above the corresponding period a year earlier. This increase was less than the rise in average earnings in manufacturing because of the increase in productivity of 2.7 per cent over this period. In the third quarter of 1991, wages and salaries per unit of output in the whole economy were 7.0 per cent above the corresponding period a year earlier. This increase was below the rise in average earnings because of the rise of about 0.6 per cent in productivity over this period.

Monetary aggregates

Provisional information suggests that in the 12 months to December, and before seasonal adjustment, M0 increased by 3.0 per cent, and M4 by 6.1 per cent. In December, again before seasonal adjustment, M0 increased by 7.1 per cent, and M4 increased by 0.9 per cent. After seasonal adjustment, M0 rose by 0.3 per cent, and M4 rose by 0.8 per cent.
